Reasoning about Effect Interaction by Fusion

ZHIXUAN YANG, Imperial College London, United Kingdom
NICOLAS WU, Imperial College London, United Kingdom

Effect handlers can be composed by applying them sequentially, each handling some operations and leaving other operations uninterpreted in the syntax tree. However, the semantics of composed handlers can be subtle—it is well known that different orders of composing handlers can lead to drastically different semantics. Determining the correct order of composition is a non-trivial task.

To alleviate this problem, this paper presents a systematic way of deriving sufficient conditions on handlers for their composite to correctly handle combinations, such as the sum and the tensor, of the effect theories separately handled. These conditions are solely characterised by the clauses for relevant operations of the handlers, and are derived by fusing two handlers into one using a form of fold/build fusion and continuation-passing style transformation.

As case studies, the technique is applied to commutative and distributive interaction of handlers to obtain a series of results about the interaction of common handlers: (a) equations respected by each handler are preserved after handler composition; (b) handling mutable state before any handler gives rise to a semantics in which state operations are commutative with any operations from the latter handler; (c) handling the writer effect and mutable state in either order gives rise to a correct handler of the commutative combination of these two theories.

CCS Concepts: • Theory of computation → Program reasoning; Control primitives.

ACM Reference Format:

1 INTRODUCTION

 Algebraic effects [Plotkin and Power 2002] and their handlers [Plotkin and Pretnar 2009, 2013] are inherently a modular approach to modelling computational effects: algebraic theories of effects specify effects and handlers implement them. Furthermore, both algebraic theories and handlers are composable in their own right. Algebraic theories can be combined in various ways of specifying the interaction of operations of the sub-theories [Hyland et al. 2006], such as requiring operations from one sub-theory to be commutative with any operation from other theories, giving rise to the combined theory called the tensor of the sub-theories. The modularity of effect theories enables programmers to reason about programs involving complex computational effects in a modular way [Gibbons and Hinze 2011]. On the implementation side, effect handlers are composable by running them sequentially, each handling a set of operations in the computation and forwarding other operations.

However, the link between the composability on the specification side (effect theories) and the composability on the implementation side (handlers) has remained elusive. Suppose that two effect theories are combined into a bigger theory by specifying a particular way for their operations to interact. Following the modular methodology of algebraic effects, we would like to handle the combined theory by composing handlers of the sub-theories. However, it is not the case that the sequential composition of any handlers of the sub-theories automatically respects the specified interaction. Instead, additional work must be done to prove that the composite handler indeed validates the combined theory. Our goal is to minimise this additional work.

To illustrate this problem, we use a running example of the theories of mutable state and nondeterminism. The theory $\text{State}$ of mutable state consists of two operations $\text{get}$ and $\text{put}$ for reading and writing the state, and equations that characterise the properties these two operations obey (listed in full in Example 2.4), such as that the result of a read immediately following a write must be the value just written. The theory $\text{NDet}$ of nondeterministic choice has one operation $\text{coin}$ that returns a Boolean value and certain equations specifying $\text{coin}$ (Example 2.5).

These two theories can be separately handled by two handlers $h_{\text{ST}}$ and $h_{\text{ND}}$ respectively (Figure 1 shows an implementation of them in Eff [Bauer and Pretnar 2015]). The semantics of any handler $h$ is a function $\text{handle } h$ that applies the handler on computations, i.e. terms built from effectful operations and pure values, producing terms with unhandled operations. Handlers of $\text{State}$ and $\text{NDet}$ can be sequentially composed to handle both stateful and nondeterministic operations in a computation $M$, in the order that either mutable state gets handled first $\text{handle } h_{\text{ND}}(\text{handle } h_{\text{ST}} M)$ ($\text{HStNd}$) or nondeterminism gets handled first $\text{handle } h_{\text{ST}}(\text{handle } h_{\text{ND}} M)$ ($\text{HNdSt}$) and it is well known that the two orders result in different handling behaviours. On the specification side, the theories $\text{State}$ and $\text{NDet}$ can be composed into one single theory too. One desirable combination is the commutative tensor [Hyland et al. 2006], or simply tensor, of the theories $\text{State}$ and $\text{NDet}$—the theory with all the operations and equations from $\text{State}$ and $\text{NDet}$ and additionally equations stating that any operation from $\text{State}$ is commutative with any operation from $\text{NDet}$:

\begin{align*}
\text{do } \{ b \leftarrow \text{coin } (); \text{put } s; k \ b \} &= \text{do } \{ \text{put } s; b \leftarrow \text{coin } (); k \ b \} \quad (1) \\
\text{do } \{ b \leftarrow \text{coin } (); s \leftarrow \text{get } (); k \ b \ s \} &= \text{do } \{ s \leftarrow \text{get } (); b \leftarrow \text{coin } (); k \ b \ s \} \quad (2)
\end{align*}

Although both handlers and theories are composable, the problem is that the composabilities of handlers and theories are not automatically connected. Supposing that the tensor is the desired semantics of combining state and nondeterminism in an application, the programmer needs to pick one from $\text{HNdSt}$ and $\text{HStNd}$ and prove that it indeed validates all the equations of the tensor. Furthermore, to make the equations useful in reasoning or optimisation, one usually wants to prove that they are term congruences under the composite handler—the equation can be applied to transform terms in any context under the handler [Kiselyov et al. 2021].

The conventional way to show a composite handler respecting some combination of effect theories is equational reasoning with the induction principle on computations [Plotkin and Pretnar 2008]. For example, if one wants to show that the composite handler $\text{HStNd}$ validates equation (1) of the tensor, one needs to do an induction on the computation $k \ b$, where $k$ is a free variable in the equation. The base case for $k \ b$ is a pure computation returning some value, and the inductive case is $k \ b = \text{do } \{ a \leftarrow \text{op } p; k' \ a \}$, where some operation $\text{op}$ is invoked and then it acts as some computation $k'$. In either case, the proof obligation is to show that applying the handler $\text{HStNd}$ to the both sides of (1) gives rise to equivalent computations, which can be established by careful
calculation. Additionally, if one wants to show that the equation is a term congruence, an additional induction on the context where the equation is used is required. In practice, proving a composite handler respecting some combination of theories in this way can be laborious for several reasons:

- Equations proved to be respected by sub-handlers needs to be re-established for composite handlers because in general, the composite handler does not necessarily respect the equations respected by the sub-handlers (shown later in Example 3.4).
- One needs to explicitly prove that equations respected by a composite handler are term congruences under the handler since it is not true in general [Kiselyov et al. 2021].
- Some ways of combining effect theories create a large number of equations of the same form, but the common structure in these equations are not exploited.

1.1 A Taste of the Results

The aim of this paper is to develop techniques for proving the correctness of composite handlers (by correctness of handlers, we always mean validating the expected equations) with respect to combinations of effect theories in a more manageable way. For a class of handlers that are modular, as characterised by Schrijvers et al. [2019], given any combination of effect theories, we present a systematic way to devise conditions on handlers so that their composite correctly handles this combination of sub-theories. We argue that verifying these conditions is much easier than proving the correctness directly based on the definitions.

To provide a taste of the techniques developed in the paper, consider the running example in Figure 1. Suppose the programmer has proved that the handlers \( h_{ST} \) and \( h_{ND} \) are correct handlers for effect theories State and NDet respectively, and that the programmer wants to show that the composite handler \( H_{STN} \) correctly handles the commutative tensor of State and NDet.

According to the definition, the commutative tensor of State and NDet inherits all the equations in the two sub-theories, so the programmer first needs to show that the composite handler \( H_{STN} \) respects these equations. Our results can prove this almost for free: Theorem 5.5 tells us that any equations respected by modular handlers separately are still respected by their composite, and indeed both \( h_{ST} \) and \( h_{ND} \) are modular handlers. Thus without any further work, we immediately know that \( H_{STN} \) respects the equations from State and NDet because these equations are respected by \( h_{ST} \) and \( h_{ND} \) separately.

Also, the programmer needs to show that \( H_{STN} \) validates the commutativity equations (1, 2) in the tensor. The conventional way to show this is to do an induction on the free computation \( k \), apply \( H_{STN} \) to both sides of the equations, and then perform equational reasoning to establish the required equality. Although proving the correctness of composite handlers in this way is typically not difficult, the calculation can be tedious. This paper offers a more efficient way to do this: let \( c_{put} \), \( c_{get} \) and \( c_{coin} \) be the clauses (in a sense made clear in Section 5.3) of the two handlers \( h_{ST} \) and \( h_{ND} \):

\[
\begin{align*}
  &c_{put} : p_1 \ k = \lambda s \rightarrow k \ () \ p_1 \\
  &c_{get} : k = \lambda s \rightarrow k \ s \ s \\
  &c_{coin} : k = \text{do} \ \{ \ l_1 \leftarrow k \ True; \ l_2 \leftarrow k \ False; \ \text{return} \ (l_1 ++ l_2) \} 
\end{align*}
\]
Then Theorem 6.1 says that the composite handler \( H_{\text{StNd}} \) respects the required equations (1, 2) if each clause \( c_{\text{ST}} \in \{c_{\text{put}}, c_{\text{get}}\} \) of \( h_{\text{ST}} \) and each clause \( c_{\text{ND}} \in \{c_{\text{coin}}\} \) of \( h_{\text{ND}} \) satisfy the following equation for all \( p_1, p_2, k \) (the types of the variables in the equation can be ignored for now):

\[
c_{\text{ST}} p_1 (\lambda a_1 \rightarrow \lambda s q \rightarrow c_{\text{ND}} p_2 (\lambda a_2 \rightarrow k a_1 a_2 s q))
= \lambda s q \rightarrow c_{\text{ND}} p_2 (\lambda a_2 \rightarrow c_{\text{ST}} p_1 (\lambda a_1 \rightarrow k a_1 a_2 s q))
\]

(3)

Then it is straightforward calculation to check that condition (3) is satisfied for each \( c_{\text{ST}} \in \{c_{\text{put}}, c_{\text{get}}\} \) and \( c_{\text{ND}} = c_{\text{coin}} \). For example, if \( c_{\text{ST}} = c_{\text{put}} \), then

\[
c_{\text{put}} p_1 (\lambda a_1 \rightarrow \lambda s q \rightarrow c_{\text{coin}} p_2 (\lambda a_2 \rightarrow k a_1 a_2 s q)) \quad \text{\{ definition of } c_{\text{put}}\}
= \lambda s q \rightarrow c_{\text{coin}} p_2 (\lambda a_2 \rightarrow k (a_2 p_1 q) \quad \text{\{ definition of } c_{\text{put}}\}
= \lambda s q \rightarrow c_{\text{put}} p_1 (\lambda a_1 \rightarrow k a_1 a_2 s q)
\]

Finally, every equation respected by the composite of two modular handlers is automatically a term congruence under the handler (Remark 5.2), which is an important property for reasoning about effectful programs with these equations. This example will be studied in detail in Section 6.1, and the point is that this is much less of a burden than proving directly from the definitions.

The key technique underlying the results described above is handler fusion [Wu and Schrijvers 2015]: given any two modular handlers \( h_1 \) and \( h_2 \), we show that there exists a modular handler \( h_2 \odot h_1 \) such that

\[
\text{handle } h_2 \cdot \text{handle } h_1 = \text{handle } (h_2 \odot h_1)
\]

Consequently, the composite handler handle \( h_2 \cdot \text{handle } h_1 \) respects an effect theory if and only if \( h_2 \odot h_1 \) does, and the latter is easier to work with since it is a single catamorphism on syntax trees of programs. By the properties of catamorphisms, handle \( (h_2 \odot h_1) \) respects an effect theory if \( h_2 \odot h_1 \) respects it, from which we calculate conditions for handle \( h_2 \odot h_1 \) to respect various combinations of effect theories, such as Theorem 5.5 and Theorem 6.1 used in the above example, and more results are listed in Figure 2.

### 1.2 Contributions

After fixing notation for preliminary concepts (Section 2), Schrijvers et al. [2019]'s modular handlers are motivated and recalled (Section 3), and then this paper makes the following contributions:

- a characterisation of correct syntax tree transformations and correct modular handlers with a soundness theorem relating them (Section 4);
Fig. 3. Type classes for functors and monads in Haskell

- a fusion combinator (⋄) of modular handlers (Section 5) that enables us to reason about the interaction of two handlers when composing them (Corollary 5.4). Particularly, we show that equations separately respected by modular handlers are preserved after composition (Theorem 5.5);
- conditions on handlers for their composite to correctly handle the tensor of the theories (Section 6). As applications, we show that (i) handling mutable state before any handler gives rise to a semantics in which stateful operations are commutative with any operation from the latter handler (Theorem 6.5), and that (ii) handling the writer effect and mutable state in either order gives rise to a correct handler of the commutative interaction of the two theories (Theorem 6.6);
- conditions on handlers for their composite to correctly handle the distributive tensor of the theories (Section 7), and an application to the handlers of nondeterministic and probabilistic choice (Section 7.1), which exhibits a limitation of the fusion approach.

Finally, we discuss related work (Section 8) and conclude (Section 9).

2 PRELIMINARIES

Throughout this paper, we use Haskell as a vehicle to present all the constructions and results to make them more accessible to functional programmers. We restrict ourselves to a subset of Haskell that is total: all recursion is structural; recursive datatypes are inductive; and polymorphism is predicative, etc. Readers familiar with category theory can understand our notation as a metalinguage denoting constructions around the category of sets: types denote sets; inductive datatypes denote initial algebras; and polymorphic functions denote ends, etc. In this way, the results developed in this paper apply to any language implementing effect handlers that has a denotational semantics based on the constructions studied in this paper (as an illustration, Appendix F shows such a call-by-value calculus with handlers and a translation to our Haskell constructions). We hope that our notation can be a good compromise between concreteness and generality.

Functors. In Haskell, a functor \( f : \mathbb{A} \to \mathbb{A} \) is a type constructor instantiating the \textit{Functor} type class (Figure 3). It is also expected to satisfy the functor laws:

\[
\text{fmap id} = \text{id} \quad \text{fmap g} \cdot \text{fmap h} = \text{fmap} \ (g \cdot h)
\]

For any functor \( f \), we call a function of type \( f \ c \to c \) an \( f \)-algebra and type \( c \) the carrier of this \( f \)-algebra. For example, given types \( P \) and \( A \), then data \( \Sigma x = O \ P \ (A \to x) \) with the following \textit{fmap} is a functor:

\[
\text{instance Functor } \Sigma \ 
\text{where } \text{fmap f} \ (O p k) = O \ p \ (f \cdot k) \quad (4)
\]

Given any two functors \( f \) and \( g \), their coproduct \( f \oplus g \) is given by the following datatype, and it can also be equipped with a functor instance.

\[
\text{data } (f \oplus g) \ a = \text{Inl} \ (f \ a) \mid \text{Inr} \ (g \ a) \quad (5)
\]

\[
\text{fmap } h \ (\text{Inl} \ x) = \text{Inl} \ (\text{fmap} \ h \ x) \quad \text{fmap } h \ (\text{Inr} \ y) = \text{Inr} \ (\text{fmap} \ h \ x)
\]
Monads. A functor \( m \) is a monad if it instantiates the \( \text{Monad} \) type class (Figure 3) and adheres to the monad laws:

\[
\text{join} \cdot \text{return} = \text{id} \quad \text{join} \cdot \text{fmap} \ \text{return} = \text{id} \quad \text{join} \cdot \text{join} = \text{join} \cdot \text{fmap} \ \text{join}
\]

where \( \text{join} :: m (m \ a) \to m \ a \) is defined by \( \text{join} \ m = m \Rightarrow \text{id} \). Pioneered by Moggi [1991], monads are used to model computational effects. Intuitively, \( \text{return} \) turns a pure value into a trivial computation causing no effects, and \( m \Rightarrow f \) executes computation \( m \) first, letting its result be \( x \), then executes \( f \ \ x \). Additionally, Haskell supports the do-notation \( \text{do} \ x \leftarrow m; b \) as a syntactic sugar for \( m \Rightarrow (\lambda x \to b) \).

Free Monads. For any functor \( f \), the inductive datatype \( \text{Free} \ f \ v \) is called the free monad from \( f \):

\[
data \ \text{Free} \ f \ v = \text{Var} \ v \mid \text{Op} \ (f \ (\text{Free} \ f \ v))
\]

Intuitively, an element of \( \text{Free} \ f \ v \) is a tree with leaf nodes constructed by \( \text{Var} \) and internal nodes constructed by \( \text{Op} \), where the functor \( f \) determines the branching structure of internal nodes. Given an \( f \)-algebra \( \text{alg} :: f \ c \to c \) and function \( \text{gen} :: v \to c \), there is a function \( \text{fold} \) (also known as \text{catamorphism}) that recursively reduces \( \text{Free} \ f \ v \) to the carrier \( c \) of \( \text{alg} \):

\[
\text{fold} :: \text{Functor} \ f \Rightarrow (f \ c \to c) \to (v \to c) \to \text{Free} \ f \ v \to c \\
\text{fold \ alg \ gen} \ (\text{Var} \ x) = \text{gen} \ x \\
\text{fold \ alg \ gen} \ (\text{Op} \ \text{op}) = \text{alg} \ (> > \ \text{fmap} \ (\text{fold} \ \text{alg} \ \text{gen}) \ \text{op})
\]

The monad instance of \( \text{Free} \ f \) is implemented with \( \text{fold} \):

\[
\text{return} :: v \to \text{Free} \ f \ v \quad (\Rightarrow) :: \text{Free} \ f \ v \to (v \to \text{Free} \ f \ u) \to \text{Free} \ f \ u \\
\text{return} = \text{Var} \quad m \Rightarrow f = \text{fold} \ \text{Op} \ m
\]

Intuitively, \( \text{return} \ x \) is a variable \( x \), and \( m \Rightarrow f \) performs substitution of variables in \( m \) using \( f \).

2.1 Algebraic Theories

Plotkin and Power [2002] propose to model a computational effect by an \textit{algebraic theory}, which is a set of primitive effectful operations and a set of equations on those operations characterising the behaviour of the operations. In this section, we provide an account of algebraic theories in our Haskell notation as the basis for our development.

Signature Functors. A signature is a finite set of operation symbols \( \{O_i\} \), each paired with a \textit{parameter} type \( P_i \) and an \textit{arity} type \( A_i \) (or \textit{result type} by some authors). A signature with \( n \) operations can be described by a \textit{signature functor} \( \Sigma \) of the following form:

\[
data \ \Sigma \ x = O_1 P_1 (A_1 \to x) \mid O_2 P_2 (A_2 \to x) \mid \cdots \mid O_n P_n (A_n \to x)
\]

(with the evident \textit{Functor} instance similar to (4)). In this paper, we use notation \( O :: P \rightsquigarrow_{\Sigma} A \) to mean that \( O \) is an operation in \( \Sigma \) with parameter type \( P \) and arity type \( A \), i.e. there is a constructor \( O :: P \to (A \to x) \to \Sigma \ x \) for the signature functor \( \Sigma \). We sometimes omit the subscript \( \Sigma \) in \( \rightsquigarrow_{\Sigma} \) if it is clear from context. A computational interpretation of a \( P \rightsquigarrow A \) operation is an effectful computation taking a \( P \)-value and returning an \( A \)-value, or equivalently, an operation parameterised by a \( P \)-value and combining \(|A|\)-many possible ways of continuing the computation into one computation [Bauer 2018; Plotkin and Power 2004].

Example 2.1 (Nondeterministic Choice). The signature \( \text{NDet} \) of nondeterministic choice has one operation \( \text{Coin} :: () \rightsquigarrow \text{Bool} \) with \( \text{Bool} \) as its arity type. For aesthetic reasons, we prefer the infix \( (\sqcap) :: x \to x \to \text{NDet} \ x \) instead of \( \text{Coin} \), where

\[
p \sqcap q = \text{Coin} () \ (\lambda b \to \text{if} \ b \ \text{then} \ p \ \text{else} \ q)
\]
The operation *Coin* is intended to return a *Bool* value nondeterministically, or equivalently, \( p \cap q \) behaves like \( p \) or \( q \) nondeterministically.

**Example 2.2 (Mutable State).** The signature *State\(_s\)* of mutable state of type \( s \) has two operations: 
*Get* :: () ↦ \( s \) and *Put* :: \( s \) ↦ (). The operation *Get* is intended to read and return the state, and *Put* is intended to overwrite the state with its parameter of type \( s \) (and return nothing).

**Example 2.3 (Empty Theory).** Another theoretically useful algebraic theory is the trivial theory *Empty* with no operations and equations. Thus its signature functor *Empty* has no constructors.

**Equations.** An equation for a signature \( \Sigma \) is a pair of terms built from operations in \( \Sigma \) and some free variables. For example, the following is an equation for signature *State\(_s\)*:

\[
\text{Put } u (\lambda() \rightarrow \text{Put } u' (\lambda() \rightarrow k)) = \text{Put } u' (\lambda() \rightarrow k) \tag{10}
\]

where \( u, u' \) and \( k \) are free variables. Note that we have two kinds of free variables: \( k \) stands for a *computation*, whereas \( u \) and \( u' \) stands for *values* of type \( s \). One way to formalise equations is to use the *free monad* \( (\_ \vdash \_ ) \): an equation is formalised as a pair of elements of \( \Gamma \rightarrow \text{Free } \Sigma \nu \) for some types \( \Gamma \) and \( \nu \), where \( \Gamma \) is the type representing all free *value variables* and \( \nu \) is the type *indexing* all free *computation variables*:

\[
\text{data Equation } \Sigma \Gamma \nu = (\vdash) \ (\Gamma \rightarrow \text{Free } \Sigma \nu) \ (\Gamma \rightarrow \text{Free } \Sigma \nu) \tag{11}
\]

where binary operator \( \vdash \) is the constructor. Free value variables and computation variables are treated differently to leave the type of computations abstract in equations. For the example \( (10) \) above, \( \Gamma \) is \((s, s)\) since there are two free value variables of type \( s \) in the equation, and \( \nu \) is the unit type () indicating that there is one free computation variable in the equation:

\[
\text{putPutEq :: Equation State\(_s\)} (s, s) ()
\]

\[
\text{putPutEq} = ((\text{lhs} \vdash \text{rhs}) \ \text{where})
\]

\[
\text{lhs}, \text{rhs} :: (s, s) \rightarrow \text{Free State\(_s\)} ()
\]

\[
\text{lhs} (u, u') = \text{Op} (\text{Put } u (\lambda() \rightarrow \text{Op} (\text{Put } u' (\lambda() \rightarrow \text{Var} ())))))
\]

\[
\text{rhs} (u, u') = \text{Op} (\text{Put } u' (\lambda() \rightarrow \text{Var} ()))
\]

In the main text of this paper, we will stick to the informal form of equations as in \( (10) \) for brevity, and the formal form will only be used in proofs. It is straightforward to convert an informal equation to the formal form *Equation \( \Sigma \Gamma \nu \)* by collecting free variables of computations into a type \( \nu \) and free variables of values into a type \( \Gamma \) and inserting \( \text{Var} \) and \( \text{Op} \) appropriately.

**Example 2.4.** Continuing Example 2.2, the theory of mutable state traditionally comes with four equations [Plotkin and Power 2002]. Letting *Put* \( s \) \( c \) = *Put* \( s \) (\( \lambda() \rightarrow c \)) and *Get* \( k \) = *Get* () \( k \), the four equations of mutable state are

\[
\text{put } s \ (\text{get } k) = \text{put } s \ (k \ s) \quad \text{put } s \ (\text{put } s' \ k) = \text{put } s' \ k
\]

\[
\text{get} (\lambda s \rightarrow \text{get} (\lambda s' \rightarrow k \ s \ s')) = \text{get} (\lambda s \rightarrow k \ s \ s) \quad \text{get} (\lambda s \rightarrow \text{put } s \ k) = k
\]

where \( k, s \) and \( s' \) are all free variables. The type of \( k \) may be different for each equation.

**Example 2.5.** Continuing Example 2.1, the theory *NDet* of nondeterminism has as equations idempotence, symmetry and associativity of the operation \( \cap \), which are the axioms of semi-lattices:

\[
p \cap p = p \quad p \cap q = q \cap p \quad p \cap (q \cap r) = (p \cap q) \cap r
\]

where \( p, q \) and \( r \) are all free variables of computations. The three equations axiomatise the so-called *internal choice* in the literature of process algebra, thus the symbol \( \cap \) is used following Hoare [1985a] instead of the seemingly more natural \( \sqcup \), which is conventionally used for external choice.
Definition 2.1 (Equation Respecting). Given \((lhs \doteq rhs) :: \text{Equation } \Sigma \Gamma \nu\) and any \(\Sigma\)-algebra \(\text{alg} :: \Sigma c \to c\), we say that \(\text{alg}\) respects this equation if for all \(t :: \Gamma \) and \(k :: \nu \to c\),
\[
\text{fold alg } k (lhs t) = \text{fold alg } k (rhs t)
\]
In other words, substituting \(\text{alg}\) for operations in the equation and any values for the free variables in the equation gives equal results.

Example 2.6. Consider the \(\text{State}_1\)-algebra \(\text{alg}_\text{ST} :: \text{State}_1 (s \to a) \to (s \to a)\)
\[
\text{alg}_\text{ST} (\text{Put } s^1' k) = \lambda s \to k () s'
\]
\[\text{alg}_\text{ST} (\text{Get } s k) = \lambda s \to k s s
\]
It can be checked to respect all the equations in Example 2.4. For example, the first equation \(\text{put } t (\text{get } k) = \text{put } t (k t)\) is respected because for all \(k :: s \to a \) and \(t :: s\),
\[
\text{fold alg } k (lhs t) = \text{fold alg}_\text{ST} k (\text{Op } (\text{Put } t (\lambda \ell) \to \text{Op } (\text{Get } () (\lambda s \to \text{Var } s))))
\]
\[= \{ \text{ recursively fold the Get } \}
\[\text{fold alg}_\text{ST} k (\text{Op } (\text{Put } t (\lambda \ell) \to (\lambda s \to k s s))))
\]
\[= \lambda s \to k t t
\]
\[= \text{fold alg}_\text{ST} k (\text{Op } (\text{Put } t (\lambda \ell) \to \text{Var } t))) = \text{fold alg } k (rhs t)
\]

Example 2.7. Given any semi-lattice \(\langle L, \cup \rangle\), the equations in Example 2.5 are respected by the \(\text{NDet}\)-algebra \(\text{alg} (\text{Coin } (k)) = k \text{ True } \cup k \text{ False}\).

Definition 2.2 (Algebraic Theories). An algebraic theory \(T\) is a signature functor \(\Sigma\) equipped with a set of equations of type \(\text{Equation } \Sigma \Gamma \nu\) for some types \(\Gamma \) and \(\nu\)’s (different equations may have different \(\Gamma\) and \(\nu\)’s). We use the notation \(T :: \text{Theory } \Sigma\) to mean a theory \(T\) of signature \(\Sigma\).

Algebraic theories are also known as \textit{equational theories}, which are equivalent to \textit{Lawvere theories} that present theories as categories [Plotkin and Power 2004]. When the associated equations are clear, we sometimes abuse the name of a signature functor to mean a theory of this signature. For example, when we say the theory \(\text{State}_1\) in the rest of the paper, we mean the theory of signature \(\text{States}\) and the four equations in Example 2.4.

2.2 Combinations of Theories

Hyland et al. [2006] show how algebraic theories can be combined in various ways to specify the operations and equations of the combined theory based on the sub-theories. In this section, we reformulate the \textit{sum, tensor} and \textit{distributive tensor} [Plotkin and Power 2004] in our simplified setting for convenience.

For all the ways of combining effect theories in this paper, the operations of the combined theory are the disjoint union of the operations of the sub-theories, i.e. the signature functor of the combined theory is the coproduct (5) of the signature functors of the sub-theories. Equations of the combined theory have greater freedom of choice. A straightforward choice is just taking the union of the equations of the sub-theories and no more, which is called the \textit{sum} of the sub-theories.

Definition 2.3 (Sum of Theories [Hyland et al. 2006]). The \textit{sum} of \(T_1 :: \text{Theory } \Sigma_1\) and \(T_2 :: \text{Theory } \Sigma_2\), denoted \(T_1 + T_2\), is the theory of signature \(\Sigma_1 + \Sigma_2\) with exactly the equations of \(T_1\) and \(T_2\) (regarded as equations on signature \(\Sigma_1 + \Sigma_2\)).

One can also include equations in the combined theory to specify interactions between operations from the sub-theories, such as commutativity between operations from sub-theories.
Definition 2.4 (Tensor of Theories [Hyland et al. 2006]). The commutative combination or tensor of $T_1 :: Theory \Sigma_1$ and $T_2 :: Theory \Sigma_2$, denoted $T_1 \otimes T_2$, is the theory of signature $\Sigma_1 + \Sigma_2$ with all equations of $T_1$ and $T_2$, and for each $O_1 :: P_1 \sim \Sigma_1$, $A_1$ and $O_2 :: P_2 \sim \Sigma_2$, $A_2$, a commutativity law:

$$\overline{O}_1 p_1 (\lambda a_1 \to \overline{O}_2 p_2 (\lambda a_2 \to k a_1 a_2)) = \overline{O}_2 p_2 (\lambda a_2 \to \overline{O}_1 p_1 (\lambda a_1 \to k a_1 a_2))$$

where $\overline{O}_1 p k = \text{Inl} (O_1 p k)$ and $\overline{O}_2 p k = \text{Inr} (O_2 p k)$ lift $O_1$ and $O_2$ as operations in signature $\Sigma_1 + \Sigma_2$, and $p_1 :: P_1$, $p_2 :: P_2$ and $k$ are free variables.

Example 2.8. When a program involves two mutable states that are independent of each other, we can model the situation by the tensor $\text{State}_a \otimes \text{State}_b$ of two mutable states, since the order of two consecutive operations on independent mutable states can be swapped without changing the semantics of the computation, as long as the parameter of the second operation does not depend on the result of the first operation.

Another combination that we are going to discuss in Section 7 is adding distributivity laws in the combination. Distributivity is commonly stated for binary operations, such as for $+ \times$, $x_1 \times (y_1 + y_2) = (x_1 \times y_1 + x_1 \times y_2) \quad (y_1 + y_2) \times x_2 = (y_1 \times x_2 + y_2 \times x_2)$

By passing all operands by a function as we do in signature functors, the distributive laws generalise to operations $O_1 :: P_1 \sim A_1$ and $O_2 :: P_2 \sim A_2$ with possibly infinite arity:

$$O_1 p_1 (\lambda a_1 \rightarrow \text{if } a_1 \equiv b \text{ then } k_1 a_1) = O_2 p_2 (\lambda a_2 \rightarrow \text{else } k_2 a_2 \text{ then } k_1 a_1)$$

where computations $k_1$ and $k_2$ and values $p_1 :: P_1$, $p_2 :: P_2$ and $b :: A_1$ are free variables. Intuitively, variable $b$ marks the position of the inner computation $O_2$. Thus (12) implies distributivity laws for all positions of $O_2$ inside $O_1$.

Definition 2.5 (Distributive Tensor [Plotkin and Power 2004]). The distributive combination or distributive tensor of $T_1 :: Theory \Sigma_1$ and $T_2 :: Theory \Sigma_2$, denoted $T_1 \triangleright T_2$, is the theory of signature $\Sigma_1 + \Sigma_2$ with all equations of $T_1$ and $T_2$ and additionally for each $O_1 :: P_1 \sim \Sigma_1$, $A_1$ and $O_2 :: P_2 \sim \Sigma_2$, $A_2$, the distributive law (12) of $O_1$ over $O_2$ (lifted to be operations in $\Sigma_1 + \Sigma_2$ as in Definition 2.4).

Example 2.9 (Combined Choice). Some nondeterministic systems involve probabilistic behaviour too. The theory $\text{Prob}$ of probabilistic choice has a binary operation $\text{PChoose} :: \text{Real} \sim \text{Bool}$ with a Real parameter in the range $[0, 1]$. Operation $\text{PChoose} \ θ k$ is preferably written in infix notation $p <\text{θ}^\triangleright q = \text{PChoose} \ θ (λ b \rightarrow \text{if } b \text{ then } p \text{ else } q)$ following Hoare [Hoare 1985b]. Letting $θ$ denote $1 - θ$, theory $\text{Prob}$ has the following equations:

$$p <1^\triangleright q = p \quad p <\text{θ}^\triangleright p = p \quad p <\text{θ}^\triangleright q = q <\text{θ}^\triangleright p$$

$$p <\text{θ}^\triangleright (q <\text{θ}^\triangleright r) = (p <\text{θ}^\triangleright q) <\text{θ}^\triangleright r \quad (θ_1 = δ_1 δ_2, δ_2 = \overline{θ_1}, \overline{θ_2})$$

For a system involving nondeterministic choice and probabilistic choice, one desirable interaction of the two effects is the distributive tensor of $\text{Prob}$ over $\text{NDet}$ [Mislove et al. 2004], i.e. operations and equations from both theories with additional equations:

$$p <\text{θ}^\triangleright (q \triangleright r) = (p <\text{θ}^\triangleright q) \triangleright (p <\text{θ}^\triangleright r) \quad (p \triangleright q) <\text{θ}^\triangleright r = (p <\text{θ}^\triangleright r) \triangleright (q <\text{θ}^\triangleright r)$$

3 SYNTAX AND SEMANTICS OF COMPUTATIONS

Now that we have theories of effects, we continue to set the stage by showing how one can formalise the syntax and semantics of computations involving effects. Given an effect theory, the syntax of computations involving the effect is modelled by terms built from operations of the theory.
(Section 3.1), and semantics is provided by handlers that interpret operations in syntax trees by fold (Section 3.2). However, we show that the traditional formulation of handlers lacks modularity when the effect theory is composed from sub-effects. Particularly, equations respected by one handler may be invalidated by other handlers when composing handlers together. The problem motivates modular handlers [Schrijvers et al. 2019], which ensure handlers to work independently of each other by parametricity (Section 3.3) and play a crucial role in later sections.

3.1 Terms of Computations

Given a signature \( \Sigma \), computations that involve operations in \( \Sigma \) and produce values of type \( a \) are modelled by the free monad \( \text{Free} \Sigma a \) (7). An element of \( \text{Free} \Sigma a \) is either \( \text{Var} \ x \), which represents a pure computation returning \( x \), or \( \text{Op} \ (O \ p \ k) \) for some \( O :: P \rightsquigarrow_\Sigma A \), \( p :: P \) and \( k :: A \to \text{Free} \Sigma a \), which represents a computation making an operation call \( O \) with parameter \( p \) and continuing as \( k \ x \) when the result of the operation is \( x :: A \).

Recall that \( \text{Free} \Sigma \) is a monad (9), and its \( \gg \) precisely means sequential composition of operations when understanding \( \text{Free} \Sigma \) as computations. For any operation \( O_g :: P \rightsquigarrow \Sigma A \), we have a function \( O_g :: P \to \text{Free} \Sigma A \), called a generic operation [Plotkin and Power 2003], such that \( O_g \ p = \text{Op} \ (O \ p \ \text{Var}) \). Generic operations and the monadic instance of \( \text{Free} \Sigma \) usually allow one to build computation terms more easily than directly using the underlying constructors.

Example 3.1. The following computation \( \text{incr} :: \text{Free} \text{State}_\text{Int} \text{Int} \) gets the state, increments it and returns the original value:

\[
\text{incr} = \text{Op} \ (\text{Get} \ () \ (\lambda i \to \text{Op} \ (\text{Put} \ (i + 1) \ (\lambda () \to \text{Var} \ i))))
\]

Using generic operations, \( \text{incr} \) can be conveniently written as \( \text{do} \ i \leftarrow \text{Get}_g \ () ; \text{Put}_g \ (i + 1) ; \text{return} \ i \).

The equations of an effect theory indicate that some computations should be deemed as equivalent, which is captured by the following relation on computations.

**Definition 3.1 (Equivalent Computations).** Given a theory \( T :: \text{Theory} \Sigma \) and a type \( a \), we define a binary relation \( \sim_T \) on elements of \( \text{Free} \Sigma a \) inductively by the following rules:

\[
\begin{align*}
&\frac{c :: \text{Free} \Sigma a}{c \sim_T c} \quad \text{REFL} \\
&\frac{c \sim_T d}{d \sim_T c} \quad \text{SYM} \\
&\frac{c \sim_T d \quad d \sim_T e}{c \sim_T e} \quad \text{TRANS} \\
&\frac{(O_1 :: P \rightsquigarrow A) \in \Sigma \quad \forall x :: A. \ k \ x \sim_T k' \ x}{\text{Op} \ (O_1 \ p \ k) \sim_T \text{Op} \ (O_1 \ p \ k')} \quad \text{CONG} \\
&\frac{(lhs = rhs) :: \text{Equation} \Sigma \Gamma V \in T \quad g :: \Gamma \quad k :: V \to \text{Free} \Sigma a}{\text{fold} \ \text{Op} \ k \ (lhs \ g) \sim_T \text{fold} \ \text{Op} \ k \ (rhs \ g)} \quad \text{EQ}
\end{align*}
\]

Relation \( c \sim_T d \) captures the idea of two computations being equivalent under theory \( T \). The first three rules make it an equivalence relation; rule \( \text{CONG} \) makes it compatible with the structure of free monad, i.e. a term congruence—whenever \( k \) and \( k' \) are equivalent terms, enclosing them in all contexts \( \text{Op} \ (O_1 \ p \ _\_ \ ) \) is still equivalent; the rule \( \text{EQ} \) asserts that instantiating equations \( lhs = rhs \) from the theory \( T \) with any value \( g \) and subterms \( k \) gives rise to equivalent computations.

Example 3.2. Consider the theory \( \text{State}_s \) from Example 2.4 and computation

\[\text{incr'} = \text{do} \ i \leftarrow \text{Get}_g \ () ; \text{Put}_g \ (i + 1) ; \text{Put}_g \ (i + 1) ; \text{return} \ i\]

With the theory \( \text{State}_\text{Int} \) from Example 2.4, it is derivable that

\[\text{do} \ \{ \text{Put}_g \ (i + 1) ; \text{Put}_g \ (i + 1) ; \text{return} \ i \} \sim_{\text{State}_\text{Int}} \text{do} \ \{ \text{Put}_g \ (i + 1) ; \text{return} \ i \} \]
using the Eq rule and the second equation in Example 2.4. Then using the Cong rule, it is derivable that \( \text{incr}' \sim_{\text{State}_{\text{Det}}} \text{incr} \) for the \text{incr} from Example 3.1.

The relation \( \sim_{\Sigma} \) plays an important role in the separation of specification and implementation of algebraic effects. The ‘user’ of effects uses relation \( \sim_{\Sigma} \) to reason about and optimise programs without knowing how effect operations are implemented, and the ‘implementer’ of effects is responsible for the correctness of the implementation with respect to the relation \( \sim_{\Sigma} \).

### 3.2 Traditional Handlers and Non-Modularity

Assuming an effect signature \( \Sigma \), the simplest form of a handler is a pair of two functions \( \text{gen} :: a \rightarrow \text{Free } \Sigma \ a \) and \( \text{alg} :: \Sigma (\text{Free } \Sigma \ b) \rightarrow \text{Free } \Sigma \ b \) for some types \( a \) and \( b \). We call \( (\text{gen}, \text{alg}) \) a handler from \( a \) to \( b \). It induces a function \( \text{handleTr} \ (\text{gen}, \text{alg}) :: \text{Free } \Sigma \ a \rightarrow \text{Free } \Sigma \ b \) that applies the handler to a computation \( \text{Free } \Sigma \ a \) by \( \text{handleTr} \ (\text{gen}, \text{alg}) = \text{fold} \ \text{alg} \ \text{gen} \), or more explicitly,

\[
\begin{align*}
\text{handleTr} \ (\text{gen}, \text{alg}) \ (\text{Var} \ x) & = \text{gen} \ x \\
\text{handleTr} \ (\text{gen}, \text{alg}) \ (\text{Op} \ (O \ p \ k)) & = \text{alg} \ (O \ p \ (\text{handleTr} \ (\text{gen}, \text{alg}) \cdot k))
\end{align*}
\]

for each operation \( O \) in \( \Sigma \). The \( \text{gen} \) function corresponds to the ‘return clause’ of handlers in Eff [Bauer and Pretnar 2015] that transforms a pure \( a \)-value \( \text{Var} \ x \) to a computation of a \( b \)-value. The \( \text{alg} \) function is the ‘operation clauses’ transforming an operation call \( O \ p \ k \) with its continuations \( k \) for all possible results of this operation to a computation of a \( b \)-value.

**Example 3.3.** Assuming \( \Sigma = \text{State}_s + \text{NDet} \) and a datatype \( \text{Set} \ a \) whose elements are subsets of the set denoted by \( a \), then \( (\text{gen}_{\text{ND}}, \text{alg}_{\text{ND}}) \) below is a handler from \( a \) to \( \text{Set} \ a \):

\[
\begin{align*}
\text{gen}_{\text{ND}} \ x & = \text{return} \ \{ \ x \} \\
\text{alg}_{\text{ND}} \ (\text{Inl} \ \text{op}) & = \text{Op} \ (\text{Inl} \ \text{op}) \\
\text{alg}_{\text{ND}} \ (\text{Inr} \ (\text{Coin} \ c \ k)) & = \text{do} \ \{ \ l_1 \leftarrow \text{True}; \ l_2 \leftarrow \text{False}; \ \text{return} \ (l_1 \cup l_2) \}
\end{align*}
\]

Note how \( \text{alg} \) forwards any operation not in \( \text{Coin} \) using \( \text{Op} \).

**Non-Modularity.** This formulation of handlers is suitable for giving denotational semantics to calculi of effect handlers that assume a global signature of effects and do not come with a type-and-effect system, such as the original one in [Plotkin and Pretnar 2009]. However, this simple formulation suffers from the problem that a handler of a signature can potentially alter operations not expected to be handled by it, breaking the modular principle followed by algebraic effects and causing difficulties in reasoning. We demonstrate the problem in the following example.

**Example 3.4.** Assuming \( \Sigma = \text{State}_s + \text{NDet} \), consider the following handler \( (\text{gen}_{\text{ND}}', \text{alg}_{\text{ND}}') \)

\[
\begin{align*}
\text{gen}_{\text{ND}}' \ x & = \text{return} \ \{ \ x \} \\
\text{alg}_{\text{ND}}' \ (\text{Inl} \ \text{op}) & = \text{Op} \ (\text{Inl} \ \text{op}) \\
\text{alg}_{\text{ND}}' \ (\text{Inr} \ (\text{Coin} \ c \ k)) & = \text{do} \ \{ \ l_1 \leftarrow \text{fold} \ \text{alg}' \ \text{Var} \ (k \ \text{True}); \ l_2 \leftarrow \text{False}; \ \text{return} \ (l_1 \cup l_2) \}
\end{align*}
\]

where \( \text{alg}' \ x = \text{case} \ x \ of \ \{ (\text{Inl} \ (\text{Put} \ s \ k)) \rightarrow k; \_ \rightarrow \text{Op} \ x \}
\]

which handles \( \text{NDet} \) but additionally erases every call to \( \text{Put} \) in the first branch of nondeterministic choice using a \text{fold}. Compared to \( (\text{gen}_{\text{ND}}, \text{alg}_{\text{ND}}) \) from Example 3.3, \( (\text{gen}_{\text{ND}}', \text{alg}_{\text{ND}}') \) is less modular because it not only handles \( \text{NDet} \) but also alters operations not in \( \text{NDet} \). Consequently, \( (\text{gen}_{\text{ND}}', \text{alg}_{\text{ND}}') \) interacts less nicely with other handlers. To see this, consider the following handler \( (\text{gen}_{\text{ST}}, \text{alg}_{\text{ST}}) \) from \( a \) to \( s \rightarrow \text{Free} \ (\text{State}_s + \text{NDet}) \ a \):

\[
\begin{align*}
\text{gen}_{\text{ST}} \ x & = \text{return} \ (\lambda s \rightarrow \text{return} \ x) \\
\text{alg}_{\text{ST}} \ (\text{Inl} \ (\text{Get} \ (k) \ s)) & = \text{return} \ (\lambda s \rightarrow \text{do} \ f \leftarrow k \ s; \ s) \\
\text{alg}_{\text{ST}} \ (\text{Inl} \ (\text{Put} \ s' \ k)) & = \text{return} \ (\lambda s \rightarrow \text{do} \ f \leftarrow k \ (\cdot); \ s')
\end{align*}
\]
\[ \text{alg}_{\text{ST}} (\text{Inr } op) = \text{Op} (\text{Inr } op) \]

which respects all the equations of \text{State} in Example 2.4. However, the composite handler

\[ \text{handleTr} \left( \text{gen}_{\text{ST}}, \text{alg}_{\text{ST}} \right) \cdot \text{handleTr} \left( \text{gen}_{\text{ND}^\prime}, \text{alg}_{\text{ND}^\prime} \right) \]

no longer respects the first equation \( \text{put} s \ (\text{get } k) = \text{put} s \ (k \ s) \) because the left-hand side is transformed to \( \text{Var} (\lambda s_0 \rightarrow k \ s_0) \), while the right-hand side is transformed to \( \text{Var} (\lambda s_0 \rightarrow k \ s) \), which are not equal in general.

In general, even when \((\text{gen}_1, \text{alg}_1)\) and \((\text{gen}_2, \text{alg}_2)\) respect effect theories \(T_1\) and \(T_2\) respectively, it is not guaranteed that their composite handler respects all the equations in \(T_1\) and \(T_2\), which hinders modular reasoning about effect handlers.

### 3.3 Modular Carriers and Handlers

The problem in the last subsection can be rectified by restricting handlers to modular handlers introduced by Schrijvers et al. [2019]. The key idea is to require handlers to be explicit about what operations got handled and be polymorphic (or natural in categorical terminology) in unhandled operations so that a handler cannot alter unhandled operations arbitrarily, precluding handlers such as \((\text{gen}_{\text{ND}^\prime}, \text{alg}_{\text{ND}^\prime})\).

One seemingly reasonable way to achieve this is to require the \text{alg} function of a handler of signature \(\text{sig}\) to type \(b\) to have type

\[ \text{alg} :: \forall \text{sig}' . \text{sig} (\text{Free sig}' \ b) \rightarrow \text{Free sig}' \ b \]

so that \text{alg} is polymorphic in the signature \(\text{sig}'\) of unhandled operations. Although this restriction precludes \((\text{gen}_{\text{ND}^\prime}, \text{alg}_{\text{ND}^\prime})\), this type of \text{alg} still exposes the fact that the result is a free monad \(\text{Free sig}' \ b\), and therefore \text{alg} can still alter the tree structure of \(\text{Free sig}' \ b\), such as duplicating and removing nodes in a \(\text{Free sig}' \ b\) while being polymorphic in \(\text{sig}'\). One way to fix this is to increase the level of abstraction by replacing \(\text{Free sig}' \ b\) with an abstract monad \(m\):

\[ \text{alg} :: \forall m . \text{Monad } m \Rightarrow \text{sig} (m \ b) \rightarrow m \ b \]  \hspace{1cm} (13)

so that \text{alg} is polymorphic in a monad \(m\) representing the remaining computational effects in the computation. This idea is further generalised by Schrijvers et al. [2019] to modular carriers, which is a type \(c \ m\) parameterised by a monad \(m\) that represents the remaining computational effects in the computation, and moreover, \(c \ m\) should provide a way to forward operations in \(m\).

**Definition 3.2** (Modular Carriers [Schrijvers et al. 2019]). Type constructor \(c :: (*) \rightarrow *\) is a modular carrier if it instantiates the following type class

\[ \text{class MCarrier } c \text{ where fwd :: Monad } m \Rightarrow m (c \ m) \rightarrow c \ m \]

subject to the laws of Eilenberg-Moore algebras [Mac Lane 1998], i.e. for every monad \(m\),

\[ \text{fwd} \cdot \text{return} = \text{id} \quad \text{fwd} \cdot \text{fmap } \text{fwd} = \text{fwd} \cdot \text{join} \]  \hspace{1cm} (14)

The first equation is on type \(c \ m \rightarrow c \ m\), and it states that forwarding a trivial computation created by \text{return} does nothing. The second one is on type \(m \ (c \ m) \rightarrow c \ m\), and it states that forwarding two layers of computational effects one-by-one is equivalent to forwarding the sequential composition of them.

**Example 3.5.** A straightforward but useful modular carrier is

\[ \text{newtype FreeEM } a \ m = \text{FreeEM} \ \{ \text{unFreeEM} :: m \ a \} \]
in the record syntax of Haskell, which defines a constructor and destructor of the following types:

\[
\text{FreeEM} :: m a \to \text{FreeEM} a m \\
\text{unFreeEM} :: \text{FreeEM} a m \to m a
\]

It is a modular carrier with the following \textit{fwd}:

\[
\text{instance MCarrier (FreeEM a) where } \text{fwd} = \text{FreeEM} \cdot \text{join} \cdot \text{fmap unFreeEM}
\]

The laws of monads in (6) imply that the laws in (14) are satisfied. The name \textit{FreeEM} comes from the fact that \text{FreeEM} \ a \ m \equiv \ m \ a \ with \ join \ is \ the \ free \ Eilenberg-Moore \ algebra \ for \ a. \ The \ scheme \ in \ (13) \ is \ then \ equivalent \ to \ \text{alg} :: \forall m. \ \text{Monad} \ m \Rightarrow \text{sig (FreeEM b m)} \to \text{FreeEM b m}.

\textbf{Example 3.6.} Another modular carrier is a family of computations indexed by some type \(s\):

\[
\text{newtype StateC s a m} = \text{StateC} \{ \text{unStateC} :: s \to m a \}
\]

\text{instance MCarrier (StateC s a) where } \text{fwd mc} = \text{StateC (} \lambda s \to (\text{do} \{ f \leftarrow mc; \text{unStateC f s} \}) \text{)}
\]

This carrier is useful for interpreting handlers with parameters [Brady 2013; Kammar et al. 2013]. We will use this carrier for the handler of mutable state very soon.

The \textit{fwd} function of a modular carrier is polymorphic in any monad \(m\). In particular, when \(m\) is \text{Free sig}'\, the following function is able to forward one operation call:

\[
\text{forward} :: (\text{MCarrier c, Functor sig}') \Rightarrow \text{sig'} (c (\text{Free sig}') \to c (\text{Free sig}')) \\
\text{forward op} = \text{fwd (Op (fmap return op))}
\]

\textbf{Definition 3.3 (Modular Handlers [Schrijvers et al. 2019]).} Given a signature \(\text{sig}\), a \textit{modular handler} \(h\) for \(\text{sig}\) from type \(a\) to \(b\) carried by modular carrier \(c\) consists of three functions (\text{gen}, \text{alg}, \text{run}) packed into the following record:

\[
\text{data MHandler sig c a b = MHandler} \{ \text{gen} :: \forall m. \ \text{Monad} \ m \Rightarrow a \to c m \\
, \text{alg} :: \forall m. \ \text{Monad} \ m \Rightarrow \text{sig (c m)} \to c m \\
, \text{run} :: \forall m. \ \text{Monad} \ m \Rightarrow c m \to m b \}
\]

which induces a function (\textit{handle} \(h\)) \(:: \forall \text{sig'}\). \text{Free (sig + sig')} \ a \to \text{Free sig}’ \ b\ such that

\[
\text{handle} h = \text{run} \cdot \text{fold alg'} \cdot \text{gen}
\]

where \(\text{alg'} (\text{Inl op'}) = \text{alg op'}\) and \(\text{alg'} (\text{Inr op'}) = \text{forward op'}\).

The \textit{gen} and \textit{alg} functions of a modular handler play similar roles as in traditional handlers. The \textit{run} function additionally allows a modular handler to do some post-processing after the fold, such as providing an initial state to a parameterised handler.

\textbf{Example 3.7.} The handler of \textit{NDet} in \textbf{Example 3.3} can be turned into a modular handler with modular carrier \textit{FreeEM} from \textbf{Example 3.5}:

\[
\text{ndetH :: MHandler NDet (FreeEM (Set a))} \ a \ (\text{Set a}) \\
\text{ndetH} = \text{MHandler} \{ \text{gen} = \text{genND}, \ \text{alg} = \text{algND}, \ \text{run} = \text{unFreeEM} \} \ \text{where} \\
\text{genND} \ a = \text{FreeEM (return \{ a \})} \\
\text{algND} (\text{Coin} () \ k) = \text{FreeEM (do} \ l_1 \leftarrow \text{unFreeEM (k True);} \ l_2 \leftarrow \text{unFreeEM (k False); return} \ (l_1 \cup l_2))
\]

Compared to its non-modular counterpart in \textbf{Example 3.3}, \textit{algND} does not deal with forwarding unhandled operations, since they are forwarded by \textit{handle}.
Example 3.8. The handler of $\text{State}_s$ in Example 3.4 can be translated into a modular handler with modular carrier $m$ ($s \to m a$), but the outer layer of $m$ is unnecessary, and we can define the following modular handler of $\text{State}_s$ with carrier $\text{State}C s a m = s \to m a$ from Example 3.6:

$$
stH : s \to \text{MHandler State}_s (\text{State}C s a) a a
$$

$$
stH s = \text{MHandler} \{ \text{gen} = \text{gen}_{\text{ST}}, \text{alg} = \text{alg}_{\text{ST}}, \text{run} = (\lambda c \to \text{unStateC} c s) \} \text{ where}
$$

$$
\text{gen}_{\text{ST}} a = \text{StateC} (\lambda s \to \text{return} a)
$$

$$
\text{alg}_{\text{ST}} (\text{Put} s' k) = \text{StateC} (\lambda s \to \text{unStateC} (k()) s')
$$

$$
\text{alg}_{\text{ST}} (\text{Get}()) k = \text{StateC} (\lambda s \to \text{unStateC} (k s) s)
$$
The handler takes an additional parameter of $s$ that is used as the initial state by the run function.

4 CORRECTNESS OF TRANSFORMATIONS AND HANDLERS

A notable missing part in the formulation of modular handlers in the previous section (and [Schrijvers et al. 2019]) is how modular handlers interact with the equations of effect theories. In this section, we recover the missing link between modular handlers and equations by defining notions of correctness of syntax-tree transformations and handlers with respect to effect theories.

Definition 4.1 (Correct Open Transformations). Given a theory $T$ of signature $\Sigma$ and a function $f$ of type $\text{Vsig}'$. Free $(\Sigma + \text{sig}') a \to \text{Free sig}' b$ for some types $a$ and $b$, we say that $f$ is a correct open transformation for $T$ if for all signatures $\text{sig}'$, theories $T' :: \text{Theory sig}'$ and computations $t_1, t_2 :: \text{Free} (\Sigma + \text{sig}') a$,

$$
t_1 \sim_{T+T'} t_2 \implies f t_1 \sim_{T'} f t_2
$$

where $T + T'$ is the sum of $T$ and $T'$ (Definition 2.3).

Under a correct open transformation for $T$, the programmer can freely use the equations from $T$ to rewrite the operations from $T$ in syntax trees in the presence of operations from other theories. A weaker notion of correctness is desired when a function on syntax trees is expected only to be used in the absence of any other effects.

Definition 4.2 (Correct Closed Transformations). Assuming $T$ and $f$ as in Definition 4.1, we call $f$ a correct closed transformation for $T$ if for all computations $t_1, t_2 :: \text{Free} (\Sigma + \text{Empty}) A$,

$$
t_1 \sim_{T+\text{Empty}} t_2 \implies \text{extract} (f t_1) =_B \text{extract} (f t_2)
$$

where extract :: Free Empty $a \to a$ is defined by extract (Var $a$) = $a$.

Remark 4.1. The definition of open correctness implies closed correctness by instantiating $T'$ with the empty theory $\text{Empty}$.

The correctness of function handle $h$ for some modular handler $h$ is implied by the correctness of handler $h$ defined as follows.

Definition 4.3 (Correct Open and Closed Handlers). Letting $T$ be a theory of signature $\Sigma$ and $h :: \text{MHandler} \Sigma c a b$ be a modular handler, (a) we call $h$ a correct open handler of $T$ if $\text{alg} h :: \text{Monad} m \Rightarrow \Sigma (c m) \to c m$ respects (in the sense of Definition 2.1) all equations of $T$ for every monad $m$, and (b) we call $h$ a correct closed handler of $T$ if $\text{alg} h$ respects equations of $T$ when $m$ is Free Empty.

Theorem 4.1 (Soundness of Correct Handlers). Letting $T$ be a theory of signature $\Sigma$ and $h$ be a modular handler of $\Sigma$, if $h$ is a correct open (or closed) handler of $T$, then handle $h$ is a correct open (or closed) transformation of $T$.
Proof sketch. We generalise handle to work with a polymorphic term monad [Wu and Schrijvers 2015] of the remaining effects, which allows us to use parametricity to relate the free monad Free sig’ and the monad mapping X to the free model of T’ generated by X, i.e. Free sig’ X modulo relation \( \sim \). A detailed proof can be found in Appendix C.

Example 4.1. It can be checked that handler \( \text{sth} \) from Example 3.8 is a correct open handler of the theory State (Example 2.4). Consequently, handle \( \text{sth} \) is a correct open transformation for State.

Example 4.2. It can be checked that \( \text{nDetH} \) from Example 3.7 is a correct open handler of the associativity of nondeterministic choice but not the symmetric law or idempotence law from Example 2.5. This is rather expected because \( \text{alg}_{\text{ndet}} \) in Example 3.7 executes both branches of nondeterministic choice sequentially. In the open setting, each branch may invoke arbitrary computational effects, so the symmetric law and idempotence cannot hold because they imply that the two branches can be swapped or absorbed into one if they invoke the same operations. However, it is a correct closed handler for all of the laws of NDet since in the closed setting both branches must be pure.

5 FUSING MODULAR HANDLERS

Throughout the section we assume two modular handlers \( h_1 :: \text{MHandler} \Sigma_1 c_1 x y z \) and \( h_2 :: \text{MHandler} \Sigma_2 c_2 y z \) for some modular carriers \( c_1 \) and \( c_2 \) and types \( x, y, z \). Their composite

\[
\text{handle } h_2 \cdot \text{handle } h_1 :: \forall \text{sig}'. \text{Free } (\Sigma_1 + (\Sigma_2 + \text{sig}')) x \rightarrow \text{Free sig}'
\]

can interpret operations from \( \Sigma_1 + \Sigma_2 \) in syntax trees, but which theories does this transformation respect? This is the question that we answer in the rest of the paper.

The function handle \( h_2 \cdot \text{handle } h_1 \) can be more easily understood if we can find some handler \( h_3 :: \text{MHandler} (\Sigma_1 + \Sigma_2) c x z \) for some modular carrier \( c \) satisfying handle \( h_2 \cdot \text{handle } h_1 = \text{handle } h_3 \cdot \text{assoc} \) where \( \text{assoc} \) and its inverse \( \text{assoc}^-1 \) is the evident isomorphism between \( \text{Free } (\Sigma_1 + (\Sigma_2 + \text{sig}')) \) and \( \text{Free } ((\Sigma_1 + \Sigma_2) + \text{sig}') \) for all \( \Sigma_1, \Sigma_2 \) and \( \text{sig}' \). In this section, we show how this can be accomplished by fold/build fusion [Gill et al. 1993; Hinze et al. 2011] and continuation-passing style (CPS) transformation.

5.1 Carrier Fusion by CPS Transformation

The idea of fold/build fusion is that when we see an operation \( O_2 \) in the computation when running \( h_1 \), the modularity of \( h_1 \) guarantees that this operation will be handled later by \( h_2 \). Thus instead of leaving \( O_2 \) in the computation, we would like to handle it directly using \( \text{alg} h_2 \) in the fold of \( h_1 \), thus fusion the handling of \( h_1 \) and \( h_2 \) into one traversal over the syntax tree of the computation. However, this idea does not directly work because the modular carrier for \( h_2 \) is only computed from the final result of \( h_1 \), and is not available in the stage of running \( h_1 \). Fortunately, this can be solved with CPS transformation as shown by Wu and Schrijvers [2015].

Given any type \( r \), the continuation monad with result type \( r \) is

\[
\text{newtype } \text{Cont}_r a = \text{Cont } \{ \text{runCont } :: (a \rightarrow r) \rightarrow r \}
\]

(16)

Intuitively, a computation of some \( a \) value in the continuation monad \( \text{Cont}_r a \equiv (a \rightarrow r) \rightarrow r \) does not necessarily compute an \( a \)-value, but instead it computes an \( r \)-value given a continuation \( a \rightarrow r \). The monad instance of \( \text{Cont}_r \) is witnessed by:

\[
\begin{align*}
\text{return } :: a \rightarrow \text{Cont}_r a \\
(\Rightarrow) :: \text{Cont}_r a \rightarrow (a \rightarrow \text{Cont}_r b) \rightarrow \text{Cont}_r b \\
\text{return } x = \text{Cont } (\lambda k \rightarrow k x) \\
\end{align*}
\]

\[
\begin{align*}
m \Rightarrow f = \text{Cont } (\lambda k \rightarrow \text{runCont } m (\lambda x \rightarrow \text{runCont } (f x) k))
\end{align*}
\]

The pure computation \( \text{return} \ x \) simply supplies \( x \) to the continuation. Monadic bind \( m \Rightarrow f \) runs \( m \) with a continuation that feeds the result \( x \) of \( m \) to \( f \) and runs \( f \) with the given continuation \( k \), so
bind is sequential composition. The continuation monad makes the final result type \( r \) explicit, and one can operate on the final result when it is not actually computed yet, which is demonstrated in the following minimal example.

**Example 5.1.** The following function \( \text{incrCont} :: \text{Cont}_{\text{Int}} \, a \rightarrow \text{Cont}_{\text{Int}} \, a \) takes a computation in the continuation monad \( \text{Cont}_{\text{Int}} \) and increments the integer that will be eventually computed.

\[
\text{incrCont} \, m = \text{Cont} \, (\lambda k \rightarrow (\text{runCont} \, m \, k) + 1)
\]

By definition, it satisfies that for any \( k \), \( \text{runCont} (\text{incrCont} \, m) \, k = (\text{runCont} \, m \, k) + 1 \).

Back to the problem of fusing handlers, when running the first handler \( h_1 \), we can take the final result type \( r \) to be the carrier \( c_2 \, m \) of the second handler \( h_2 \), since \( c_2 \, m \) is what will be eventually computed from the result of handling \( h_1 \). Furthermore, when we see an operation handled by \( h_2 \), now we can let \( h_2 \) act on the result type \( c_2 \, m \) of the continuation monad in the same way as in Example 5.1. This is made precise by the following lemma.

**Lemma 5.1.** Given any \( \Sigma_2 \)-algebra, i.e. a function \( \text{alg} :: \Sigma_2 \, r \rightarrow r \), there is a \( \Sigma_2 \)-algebra with carrier \( \text{Cont}_r \, a \) for any type \( a \) by

\[
\begin{align*}
\text{liftAlgCont} & :: \text{Functor} \, \Sigma_2 \Rightarrow (\Sigma_2 \, r \rightarrow r) \rightarrow \Sigma_2 \, (\text{Cont}_r \, a) \rightarrow \text{Cont}_r \, a \\
\text{liftAlgCont} \, \text{alg} \, s & = \text{Cont} \, (\lambda k \rightarrow \text{alg} \, (\text{fmap} \, (\lambda m \rightarrow \text{runCont} \, m \, k) \, s))
\end{align*}
\]

In particular, if \( r = c_2 \, m \), since \( \text{alg} \, h_2 :: \Sigma_2 \, (c_2 \, m) \rightarrow c_2 \, m \), then

\[
\text{liftAlgCont} \, (\text{alg} \, h_2) :: \Sigma_2 \, (\text{Cont}_{c_2 \, m} \, a) \rightarrow \text{Cont}_{c_2 \, m} \, a
\]

provides a way to handle operations from \( \Sigma_2 \) using \( \text{Cont}_{c_2 \, m} \, a \).

**Theorem 5.2 (Modular Carrier Fusion).** For any modular carriers \( c_1 \) and \( c_2 \), the data type \( c_1 \, (\text{Cont}_{c_2 \, m}) \) for any \( m \) is also a modular carrier.

**Proof.** First we note that there is a natural transformation from \( m \) to \( \text{Cont}_{c_2 \, m} \) (which is essentially Filinski [1999]’s CPS-based monadic reflection):

\[
\begin{align*}
\text{reflect}_{\text{EM}} & :: (\text{MCarrier} \, c_2, \text{Monad} \, m) \Rightarrow m \, a \rightarrow \text{Cont}_{c_2 \, m} \, a \\
\text{reflect}_{\text{EM}} \, m & = \text{Cont} \, (\lambda k \rightarrow \text{fwd}_{\text{c}_2} \, (\text{fmap} \, k \, m))
\end{align*}
\]

In fact \( \text{reflect}_{\text{EM}} \) is a monad morphism because it preserves \( \text{return} \) and \( \text{join} \) following the laws of \( \text{fwd} \) (14). Then we can define the following \( \text{MCarrier} \) instance:

\[
\begin{align*}
\text{newtype} \, \text{Fuse} \, c_1 \, c_2 \, m & = \text{Fuse} \, \{ \text{unFuse} :: c_1 \, (\text{Cont}_{c_2 \, m}) \} \\
\text{instance} \, (\text{MCarrier} \, c_1, \text{MCarrier} \, c_2) & \Rightarrow \text{MCarrier} \, (\text{Fuse} \, c_1 \, c_2) \, \text{where} \\
\text{fwd} & = \text{Fuse} \cdot \text{fwd}_{\text{c}_1} \cdot \text{fmap} \, \text{unFuse} \cdot \text{reflect}_{\text{EM}}
\end{align*}
\]

The required laws of \( \text{fwd} \) follow from the corresponding laws of \( c_1 \) and \( c_2 \) (Appendix E.1). □

### 5.2 Fused Modular Handlers

We intend to use \( \text{Fuse} \, c_1 \, c_2 \) as the modular carrier of the fused handler of \( h_1 \) and \( h_2 \), so it should carry both a \( \Sigma_r \) and a \( \Sigma_2 \)-algebra. Since \( \text{Fuse} \, c_1 \, c_2 \cong c_1 \, (\text{Cont}_{c_2 \, m}) \) and \( \text{Cont}_{c_2 \, m} \) is a monad, \( \text{alg} \, h_1 \) can be used as the \( \Sigma_r \)-algebra for \( \text{Fuse} \, c_1 \, c_2 \). Also, the \( \Sigma_2 \)-algebra \( \text{alg} \, h_2 :: \Sigma_2 \, (c_2 \, m) \rightarrow c_2 \, m \) can be lifted to \( \text{Fuse} \, c_1 \, c_2 \) in the following way:

\[
\begin{align*}
\text{liftAlgF} & :: (\Sigma_2 \, (c_2 \, m) \rightarrow c_2 \, m) \rightarrow (\Sigma_2 \, (\text{Fuse} \, c_1 \, c_2 \, m) \rightarrow \text{Fuse} \, c_1 \, c_2 \, m) \\
\text{liftAlgF} \, \text{alg} & = \text{Fuse} \cdot \text{fwd}_{\text{c}_1} \cdot \text{liftAlgCont} \, \text{alg} \cdot \text{fmap} \, (\text{return} \cdot \text{unFuse})
\end{align*}
\]
**Theorem 5.3** (Handler Fusion). For any modular handlers $h_1$ and $h_2$, it is the case that $h_2 \cdot h_1 = \text{handle} \ (h_2 \circ h_1) \cdot \text{assoc}$ where assoc is the isomorphism between $\text{Free} \ ((\Sigma_1 + \Sigma_2 + \text{sig}'))$ and $\text{Free} \ ((\Sigma_1 + \Sigma_2) + \text{sig}')$ and $h_2 \circ h_1$ is defined as follows:

\[
(\circ) \::= (\text{MCarrier} \ c_1, \text{MCarrier} \ c_2, \text{Funct} \ \Sigma_1, \text{Funct} \ \Sigma_2) \\
\Rightarrow \text{MHandler} \ \Sigma_2 \ c_2 \ y \ z \rightarrow \text{MHandler} \ \Sigma_1 \ c_1 \ x \ y \rightarrow \text{MHandler} \ ((\Sigma_1 + \Sigma_2)) \ (\text{Fuse} \ c_1 \ c_2) \ x \ z
\]

$$h_2 \circ h_1 \equiv \text{MHandler} \ \{\ \text{gen} = \text{Fuse} \cdot \text{gen} \ h_1, \ \text{alg} = \text{alg}_F, \ \text{run} = \text{run}_F\}$$

where

\[
\begin{align*}
\text{alg}_F \ (\text{Inl} \ \text{op}) &= \text{Fuse} \ (\text{alg} \ h_1 \ (\text{fmap} \ \text{unFuse} \ \text{op})) \\
\text{alg}_F \ (\text{Inr} \ \text{op}) &= \text{liftAlgF} \ (\text{alg} \ h_2) \ \text{op} \\
\text{run}_F \ x &= \text{run} \ h_2 \ (\text{runCont} \ (\text{run} \ h_1 \ (\text{unFuse} \ x)) \ (\text{gen} \ h_2))
\end{align*}
\]

**Proof Sketch.** We use the technique by Wu and Schrijvers [2015] to fuse $h_2 \cdot h_1$ into one function and show that the result is equivalent to $\text{handle} \ (h_2 \circ h_1)$. A detailed proof can be found in Appendix B. \hfill \Box

It is revealing to compare $\text{liftAlgF}$ with the $\text{forward}$ function (15) of modular handlers. Ignoring the isomorphisms $\text{Fuse}$ and $\text{unFuse}$, we can see that the $\text{Op}$ in (15) that forwards an operation call is replaced by $\text{liftAlgCont} \ \text{alg}$, which is exactly the idea of fold/build fusion.

**Corollary 5.4.** Let $h_1$ and $h_2$ be modular handlers of signatures $\Sigma_1$ and $\Sigma_2$ respectively and $T$ be any theory of signature $\Sigma_1 + \Sigma_2$. The function $h_2 \cdot h_1 \cdot \text{assoc}^\circ$ is a correct open (or closed) transformation for $T$ if $h_2 \circ h_1$ is a correct open (or closed) handler of $T$.

**Proof.** By **Theorem 5.3**, $h_2 \cdot h_1 \cdot \text{assoc}^\circ = \text{handle} \ (h_2 \circ h_1)$. Then by **Theorem 4.1**, $\text{handle} \ (h_2 \circ h_1)$ is correct for $T$ if $h_2 \circ h_1$ is correct for $T$. \hfill \Box

**Corollary 5.4** is our main tool to reason about composed transformation $h_2 \cdot h_1$ because the correctness of $h_2 \circ h_1$ is spelled by $\text{alg} \ (h_2 \circ h_1)$ (Definition 4.3), which is much simpler for calculation than $h_2 \cdot h_1$, a composite of two fold’s. As the first application, we show that $h_2 \cdot h_1$ respects equations that are respected by $h_1$ and $h_2$ separately.

**Theorem 5.5** (Preservation of Equations). Suppose $h_1$ and $h_2$ are modular handlers of signatures $\Sigma_1$ and $\Sigma_2$ respectively. If $h_1$ and $h_2$ are correct open (resp. closed) handlers of $T_1 :: \text{Theory} \ \Sigma_1$ and $T_2 :: \text{Theory} \ \Sigma_2$ correspondingly, then $h_2 \circ h_1$ is a correct open (resp. closed) handler of $T_1 + T_2$.

**Proof Sketch.** By **Definition 2.3**, an equation in $T_1 + T_2$ is either an equation from $T_1$ or an equation from $T_2$. In either case, it can be showed that $\text{alg} \ (h_2 \circ h_1)$ respects the equation. Appendix D contains a detailed proof. \hfill \Box

**Remark 5.1.** The name *modular handlers* is used by Schrijvers et al. [2019] because they allow operations to be modularly handled. The theorem above justifies the name to a greater extent: when two modular handlers are composed together, the equations from both theories are also preserved, which is not true for non-modular handlers (Example 3.4).

**Remark 5.2.** If $h_2 \circ h_1$ is correct (open or closed) for some theory $T$, then equations in $T$ are automatically term congruences under $\text{handle} \ (h_2 \circ h_1)$ (and thus $h_2 \cdot h_1$), since relation $\sim_T$ (Definition 3.1) contains the congruence rule $\text{CONG}$ and **Theorem 4.1** shows that $\text{handle} \ (h_2 \circ h_1)$ respects relation $\sim_T$. 

5.3 Clauses of Fused Handlers

Before we use $\odot$ to reason about more interactions of handlers, we calculate some bookkeeping lemmas that characterise the handling action of $h_2 \odot h_1$ on operations from the first and the second theories respectively.

**Definition 5.1** (Clauses). Let $h$ be any modular handler with modular carrier $C$. For any operation $O : P \rightsquigarrow A$ in $\Sigma$, we call the following function the clause for $O$ of $h$:

$$c :: \text{Monad } m \Rightarrow P \rightarrow (A \rightarrow C \cdot m) \rightarrow C \cdot m$$

$$c \cdot p \cdot k = \text{alg } h \circ (O \cdot p \cdot k)$$

**Lemma 5.6.** Let $h_1$ and $h_2$ be two modular handlers with modular carriers $C_1$ and $C_2$ respectively, and $c_1$ be the clause of $h_1$ for $O_1 : P_1 \rightsquigarrow A_1$ and $c_2$ be the clause of $h_2$ for $O_2 : P_2 \rightsquigarrow A_2$. Then the clause for $O_1$ of $h_2 \odot h_1$ is

$$\overline{c}_1 :: \text{Monad } m \Rightarrow P_1 \rightarrow (A_1 \rightarrow \text{Fuse } C_1 C_2 \cdot m) \rightarrow \text{Fuse } C_1 C_2 \cdot m$$

$$\overline{c}_1 \cdot p_1 \cdot k = \text{Fuse } (c_1 \cdot p_1 \cdot (\text{unFuse } \cdot k))$$

and the clause for $O_2$ of $h_2 \odot h_1$ is

$$\overline{c}_2 :: \text{Monad } m \Rightarrow P_2 \rightarrow (A_2 \rightarrow \text{Fuse } C_1 C_2 \cdot m) \rightarrow \text{Fuse } C_1 C_2 \cdot m$$

$$\overline{c}_2 \cdot p_2 \cdot k = \text{Fuse } (\text{fwd } (\text{Cont } (\lambda t \rightarrow c_2 \cdot p_2 \cdot (\lambda a_2 \rightarrow t \cdot (\text{unFuse } (k \cdot a_2)))))))$$

where binder $t$ has type $C_1 (\text{Cont}_{C_2} \cdot m) \rightarrow C_2 \cdot m$ and fwd is the following instance:

$$\text{fwd} :: \text{Cont}_{C_2} \cdot m \circ (C_1 (\text{Cont}_{C_2} \cdot m)) \rightarrow C_1 (\text{Cont}_{C_2} \cdot m)$$

This lemma can be calculated from the definition of $\text{alg } (h_2 \odot h_1)$ (Appendix E.2). It is useful to simplify $\overline{c}_2$ from Lemma 5.6 further for specific modular carriers:

**Lemma 5.7.** Assume the data in Lemma 5.6. When the modular carrier of $h_1$ is $\text{FreeEM } W$ for some type $W$, (18) is equal to

$$\overline{c}_2 \cdot p_2 \cdot k = \text{Fuse } (\text{FreeEM } (\text{Cont } (\lambda q \rightarrow c_2 \cdot p_2 \cdot (\lambda a_2 \rightarrow k' \cdot a_2 \cdot q))))$$

where $k' = \text{runCont} \cdot \text{unFreeEM} \cdot \text{unFuse} \cdot k$. And when the modular carrier of $h_1$ is $\text{StateC } S W$ for some types $S$ and $W$, (18) is equal to

$$\overline{c}_2 \cdot p_2 \cdot k = \text{Fuse } (\text{StateC } (\lambda s \rightarrow \text{Cont } (\lambda q \rightarrow c_2 \cdot p_2 \cdot (\lambda a_2 \rightarrow k' \cdot a_2 \cdot s \cdot q))))$$

where $k' \cdot a_2 \cdot s = \text{runCont} (\text{unStateC} \circ (\text{unFuse } (k \cdot a_2))) \cdot s$.

The proof for this lemma is straightforward calculation based on the definitions of fwd for FreeEM and StateC (see Appendix E.2 for details).

**Remark 5.3.** Let $h_1$ and $h_2$ be correct (open or closed) handlers of theory $T_1$ and $T_2$ respectively. With Corollary 5.4 and Lemma 5.7, we can synthesise a sufficient condition for $\text{handle } h_1 \cdot \text{handle } h_2$ to be correct for any combination of $T_1$ and $T_2$: given any equation $L = R$ involving operations from $T_1$ and $T_2$, we substitute $\overline{c}_1$ for each operation $O_1$ in $L = R$ that comes from $T_1$ and substitute $\overline{c}_2$ for each operation $O_2$ that comes from $T_2$. Then we get an equation holds if and only if $h_2 \odot h_1$ is correct for this equation by Definition 4.3, and this condition is solely characterised by the clauses for relevant operations in the equation, rather than involving the whole handler.

In the following sections, we apply this method to the commutative and distributive combinations of theories and study the correctness of the composite of some common handlers.
6 REASONING ABOUT COMMUTATIVE INTERACTION

In this section we apply the techniques developed in Section 5 to the tensor (Definition 2.4) of effect theories. We obtain a condition (20) on the clause of \( h_1 \) for \( O_1 \) and the clause of \( h_2 \) for \( O_2 \) such that operations \( O_1 \) and \( O_2 \) are commutative under the composite handler \( handle \ h_2 \cdot handle \ h_1 \). Then we use this result to study the interactions between some common handlers, specifically the handlers of mutable state, nondeterminism and the writer effect.

**Theorem 6.1.** Given \( T_1 :: Theory \ \Sigma_1 \) and \( T_2 :: Theory \ \Sigma_2 \) and \( h_1 :: MHandler \ \Sigma_1 \ C_1 \ X \ Y \) and \( h_2 :: MHandler \ \Sigma_2 \ C_2 \ Y \ Z \), if \( h_1 \) and \( h_2 \) are correct open (or closed) handlers of \( T_1 \) and \( T_2 \) respectively, a sufficient condition for \( h_2 \circ h_1 \) to be a correct open (or closed) handler of the tensor \( T_1 \otimes T_2 \) is: for each \( O_1 :: P_1 \sim \Sigma_1 \ A_1 \) and \( O_2 :: P_2 \sim \Sigma_2 \ A_2 \), letting \( c_1 \) be the clause for \( O_1 \) of \( h_1 \) and \( c_2 \) be the clause for \( O_2 \) of \( h_2 \) as in Definition 5.1, it holds that

\[
\begin{eqnarray*}
  c_1 \ p_1 \ (\lambda a_1 \to f\text{wd} (\text{Cont} \ (\lambda t \to c_2 \ p_2 \ (\lambda a_2 \to t \ (k \ a_1 \ a_2)))))) \\
  = f\text{wd} (\text{Cont} \ (\lambda t \to c_2 \ p_2 \ (\lambda a_2 \to t \ (c_1 \ p_1 \ (\lambda a_1 \to k \ a_1 \ a_2)))) (20)
\end{eqnarray*}
\]

for all \( p_1 :: P_1, p_2 :: P_2 \) and \( k :: A_1 \to A_2 \to C_1 \) (\( \text{Cont}_{C_2} \ m \)) for every monad \( m \) (or \( m = \text{Free Empty} \) for closed correctness). In (20), binder \( t \) has type \( C_1 \) (\( \text{Cont}_{C_2} \ m \) \( \to C_2 \ m \)) and \( \text{fwd} \) is the instance \( \text{fwd} :: \text{Cont}_{C_2} \ m \ (C_1 \ (\text{Cont}_{C_2} \ m)) \to C_1 \ (\text{Cont}_{C_2} \ m) \).

**Proof.** It directly follows from the characterisation of clauses for \( O_1 \) and \( O_2 \) of \( h_2 \circ h_1 \) (Lemma 5.6): substituting \( \Sigma_1 \) and \( \Sigma_2 \) in Lemma 5.6 for \( \Sigma_1 \) and \( \Sigma_2 \) in Definition 2.4 of the tensor results in (20). \( \square \)

Since \( \text{FreeEM} \) and \( \text{StateC} \) cover almost all examples of modular handlers in practice, we specialise the theorem above to these two cases and obtain conditions easier to use.

**Corollary 6.2.** When the modular carrier \( C_1 \) of \( h_1 \) is \( \text{FreeEM} \ W \ m \) for some type \( W \), we can simplify (20) with Lemma 5.7. Define \( c_1' \) and \( k' \) as follows to unwrap the constructors:

\[
\begin{eqnarray*}
  c_1' :: P_1 \to (A_1 \to (W \to C_2 \ m) \to C_2 \ m) \to (W \to C_2 \ m) \to C_2 \ m \\
  c_1' \ p \ a = \text{runCont} (\text{unFreeEM} \ (c_1 \ p \ (\text{FreeEM} \cdot \text{Cont} \cdot a))) \\
  k' :: A_1 \to A_2 \to (W \to C_2 \ m) \to C_2 \ m \\
  k' \ a_1 \ a_2 = \text{runCont} (\text{unFreeEM} \ (k \ a_1 \ a_2))
\end{eqnarray*}
\]

Then (20) is equivalent to

\[
\begin{eqnarray*}
  c_1' \ p_1 \ (\lambda a_1 \to (\lambda q \to c_2 \ p_2 \ (\lambda a_2 \to k' \ a_1 \ a_2 \ q))) \\
  = \lambda q \to c_2 \ p_2 \ (\lambda a_2 \to c_1' \ p_1 \ (\lambda a_1 \to k' \ a_1 \ a_2 \ q)) (21)
\end{eqnarray*}
\]

where binder \( q \) has type \( W \to C_2 \ m \).

**Corollary 6.3.** When the modular carrier of \( h_1 \) is \( \text{StateC} \ S \ W \ m \), (20) can be simplified with the corresponding result of Lemma 5.7 too. Define \( c_1' \) and \( k' \) as follows to unwrap the constructors:

\[
\begin{eqnarray*}
  c_1' :: P_1 \to (A_1 \to S \to (W \to C_2 \ m) \to C_2 \ m) \to (S \to (W \to C_2 \ m) \to C_2 \ m) \\
  c_1' \ p \ k = \text{runCont} \cdot \text{unStateC} (c_1 \ p \ (\lambda a \to \text{StateC} \ (\text{Cont} \cdot k \ a))) \\
  k' :: A_1 \to A_2 \to S \to (W \to C_2 \ m) \to W \\
  k' \ a_1 \ a_2 \ s = \text{runCont} (\text{unStateC} \ (k \ a_1 \ a_2) \ s)
\end{eqnarray*}
\]

Then (20) can be simplified to

\[
\begin{eqnarray*}
  c_1' \ p_1 \ (\lambda a_1 \to \lambda s \ q \to c_2 \ p_2 \ (\lambda a_2 \to k' \ a_1 \ a_2 \ s \ q)) \\
  = \lambda s \ q \to c_2 \ p_2 \ (\lambda a_2 \to c_1' \ p_1 \ (\lambda a_1 \to k' \ a_1 \ a_2) \ s \ q) (22)
\end{eqnarray*}
\]

where binder \( q :: W \to C_2 \ m \).
6.1 Combining Nondeterminism and State

Theorem 6.4. Handler \( \text{ndetH} \circ \text{stH} \) is a correct closed handler of the tensor of \( \text{NDet} \) and \( \text{State}_s \).

Proof. For each pair of \( op_1 \in \{ \text{Get}, \text{Put} \} \) and \( op_2 \in \{ \text{Coin} \} \) we verify that (22) holds. For \( op_1 = \text{Get} \) and \( op_2 = \text{Coin} \), we have

\[
\begin{align*}
\lambda q \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

For \( op_1 = \text{Put} \), \( op_2 = \text{Coin} \) and any \( p_1 : s \), we have

\[
\begin{align*}
\lambda s \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

Accordingly, we calculate:

\[
\begin{align*}
\lambda q \rightarrow k (1)
\end{align*}
\]

and the right-hand side becomes:

\[
\begin{align*}
\lambda q \rightarrow k (2)
\end{align*}
\]

Since handlers \( \text{ndetH} \) and \( \text{stH} \) are correct closed handlers for \( \text{NDet} \) and \( \text{State}_s \), we can conclude that \( \text{ndetH} \circ \text{stH} \) is a correct closed handler of the tensor of nondeterminism and mutable state.

Remark 6.1. Pauwels et al. [2019] axiomatise the local state semantics of the combination of state and nondeterminism by the sum of \( \text{State}_s \) and \( \text{NDet} \) with additionally two right-zero and right-distributive laws. Both of the additional laws can be derived from the equations of \( \text{State}_s \otimes \text{NDet} \) and algebraicity (Appendix E.3). Thus \( \text{ndetH} \circ \text{stH} \) is a correct (closed) handler of the local state semantics in [Pauwels et al. 2019].

By contrast, handling nondeterminism before state with \( \text{stH} \circ \text{ndetH} \) will not validate the conditions of the corresponding Corollary 6.2. For example, if \( op_1 = \text{Coin} \) and \( op_2 = \text{Put} \), then

\[
\begin{align*}
\lambda q \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

The left-hand side of (21) becomes

\[
\begin{align*}
\lambda q \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

and the right-hand side becomes:

\[
\begin{align*}
\lambda q \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

The arrows in the proof hints indicate the natural direction to read the calculation step.

The arrows in the proof hints indicate the natural direction to read the calculation step.

When validating \( \text{ndetH} \circ \text{stH} \), we verify that (22) holds. For \( op_1 = \text{Get} \) and \( op_2 = \text{Coin} \), we have

\[
\begin{align*}
\lambda s \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

For \( op_1 = \text{Put} \), \( op_2 = \text{Coin} \) and any \( p_1 : s \), we have

\[
\begin{align*}
\lambda s \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

Since handlers \( \text{ndetH} \) and \( \text{stH} \) are correct closed handlers for \( \text{NDet} \) and \( \text{State}_s \), we can conclude that \( \text{ndetH} \circ \text{stH} \) is a correct closed handler of the tensor of nondeterminism and mutable state.

Note that in the proof we did not rely on any property of \( c_2 \) or \( \text{ndetH} \). In fact, we can strengthen the above proof to arbitrary handler \( h \) in place of \( \text{ndetH} \).

Theorem 6.5. Given a correct open (or closed) handler \( h \) of effect theory \( T \), handler \( h \circ \text{stH} \) is a correct open (or closed) handler of the tensor of \( T \) and the theory of mutable state.

When validating \( \text{ndetH} \circ \text{stH} \), we verify the following equation:

\[
\begin{align*}
\lambda s \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

The left-hand side of (21) becomes

\[
\begin{align*}
\lambda q \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

and the right-hand side becomes:

\[
\begin{align*}
\lambda q \rightarrow k (\lambda a_1 \rightarrow \lambda a_2 \rightarrow k (a_1 a_2) q)
\end{align*}
\]

\[1\]The arrows in the proof hints indicate the natural direction to read the calculation step.

We apply the technique so far to distributive tensor of effects (Definition 2.5) in this section. We
while computation
\[
\lambda q \rightarrow \text{StateC} (\lambda s \rightarrow \text{unStateC} (c'_1 p_1 (\lambda a_1 \rightarrow k' a_1 ()) q) p_2) \quad \text{\{ definition (25) of } c'_1 \text{\}}
\]
\[
= \lambda q \rightarrow \text{StateC} (\lambda s \rightarrow \text{unStateC} (k' \text{True} ()) (\lambda l_1 \rightarrow \text{l'_False} () (\lambda l_2 \rightarrow q (l_1 \cup l_2))) p_2)
\]
The boxed parts are the difference between both sides, making (21) not hold in general. The difference
also matches our intuition: if nondeterminism is handled first, computation \{ b \leftarrow \text{coin}; \text{put } p_2; k b \} corresponding to the left-hand side is transformed to \{ \text{put } p_2; k \text{True}; \text{put } p_2; k \text{False} \} by ndetH, while computation \{ \text{put } p_2; b \leftarrow \text{coin}; k b \} corresponding to the right-hand side is transformed to \{ \text{put } p_2; k \text{True}; k \text{False} \}. This explains why the boxed part of the left-hand side is StateC (\lambda s \rightarrow \text{RB } p_2) where \text{RB} is the boxed part in the right-hand side.

Remark 6.2. Pauwels et al. [2019] axiomatise the global state semantics of the combination of
state and nondeterminism by the sum of State, and NDet in addition with the following put-or law:
\[
(Put s (\lambda()) \rightarrow m) \sqcap n = Put s (\lambda()) \rightarrow m \sqcap n
\]
It is not difficult to show that stH s \circ ndetH is a correct open handler for this law using Lemma 5.7
(Appendix E.4), and thus it is a correct closed handler of the global state semantics.

6.2 Combining State and Writer
For another example, we prove that handling the writer effect and mutable state in either order is a
correct handler of their tensor. The writer effect Writer w is parameterised by a monoid w with
unit \text{mempty} and operation \circ, and it has one operation \text{Tell } :: w \rightsquigarrow () with an accumulation law:
\[
\text{Tell } w_1 (\text{Tell } w_2 k) = \text{Tell } (w_1 \circ w_2) k
\]
The writer effect can be handled by the following handler:
\[
\text{wtH} :: \text{Monad } w \Rightarrow M\text{Handler} (\text{Writer } w) (\text{FreeEM } (a, w)) a (a, w)
\]
\[
\text{wtH} = M\text{Handler} \text{gen alg unFreeEM where}
\]
\[
\text{gen } a = \text{FreeEM } (\text{return } (a, \text{mempty}))
\]
\[
\text{alg } (\text{Tell } w k) = \text{FreeEM } (\text{do } (a, u) \leftarrow \text{unFreeEM } (k()); \text{return } (a, w \circ u))
\]
It is straightforward calculation to verify that wtH is a correct open handler of the accumulation
law (see Appendix E.5 for details).

Theorem 6.6. Both stH s \circ wtH and wtH \circ stH are correct open handlers of the tensor of mutable
state and writer.

Proof Sketch. Following Theorem 6.5, \text{wtH} \circ \text{stH} s is a correct open handler of the tensor, and
Corollary 6.2 can be used to show that \text{stH} s \circ \text{wtH} is correct. A detailed calculation can be found
in Appendix E.5.

7 REASONING ABOUT DISTRIBUTIVE INTERACTION
We apply the technique so far to distributive tensor of effects (Definition 2.5) in this section. We
present a condition similar to Theorem 6.1 on two modular handlers for their composite to be
correct with respect to the distributive tensor of the sub-theories, and a specialised version similar
to Corollary 6.2 when the modular carrier is \text{FreeEM}. Then we use the results to reason about the
correctness of composing the handlers of nondeterministic and probabilistic choice with respect to
the theory of combined choice discussed in Example 2.9.

Theorem 7.1. Given \text{T}_1::\text{Theory } \Sigma_1 \text{ and } \text{T}_2::\text{Theory } \Sigma_2 \text{ and modular handlers } \text{h}_1::\text{MHandler } \Sigma_1 \text{ C}_1 \text{ X Y}
and \text{h}_2 :: \text{MHandler } \Sigma_2 \text{ C}_2 \text{ Y Z}, if \text{h}_1 \text{ and } \text{h}_2 \text{ are correct open (or closed) handlers of } \text{T}_1 \text{ and } \text{T}_2 respectively, a sufficient condition for } \text{h}_2 \circ \text{h}_1 \text{ to be a correct open (or closed) handler of the distributive tensor

which we represent as functions $\text{Prob}$

In this subsection, we explore this question using Theorem 7.1. The handler of the two theories gives rise to such a model, i.e. handling the distributive tensor correctly.

A computation using probabilistic choice can be handled to a probability distribution of outcomes $\text{Distr} \ a$ for any $\theta \in [0,1]$:

$$d_1 +_\theta d_2 = \lambda x \to \theta \ast d_1 x + (1 - \theta) \ast d_2 x$$

Theory $\text{Prob}$ (Example 2.9) can be closed-correctly handled by running both branches in sequence and convexly combine the results:

$$\text{probH} :: \text{Eq} \ a \Rightarrow \text{MHandler} \ \text{Prob} \ (\text{Distr} \ a) \ (\text{Distr} \ a)$$

$$\text{probH} = \text{MHandler gen alg unFreeEM where}$$

$$\text{gen} \ x = \text{FreeEM} \ (\text{return} \ (\lambda y \to \text{if} \ y \equiv x \ \text{then} \ 1 \text{ else} \ 0))$$

$$\text{alg} \ (\text{PChoose} \ \theta \ k) = \text{FreeEM} \ (\text{do} \ d_1 \leftarrow \text{unFreeEM} \ (k \ True); \ d_2 \leftarrow \text{unFreeEM} \ (k \ False); \ \text{return} \ (d_1 +_\theta d_2))$$
In this section, we focus on the correctness of the composite handler \( ndetH \circ \text{probH} \) with respect to \( \text{Prob}\NDet \). Since \( \text{probH} \) has modular carrier \( \text{FreeEM} (\text{Dist}\ a) \), we can try Corollary 7.2. The corresponding clauses for \( \triangleq \) and \( \cap \) are

\[
c_1' \theta k = \lambda q \to k \text{ True} (\lambda d_1 \to k \text{ False} (\lambda d_2 \to q (d_1 +_\theta d_2))) \\
c_2 () k = \text{FreeEM} (\text{do} \{ l_1 \leftarrow \text{unFreeEM} (k \text{ True}); l_2 \leftarrow \text{unFreeEM} (k \text{ False}); \text{return} (l_1 \cup l_2) \})
\]

The left-hand side of the proof obligation (28) is

\[
c_1' \theta (\lambda a_1 \to \text{if} \ a_1 \equiv b \text{ then} \lambda q \to c_2 () (\lambda a_2 \to k_2' a_2 \ q) \text{ else} k_1' a_1) \quad \{ \text{definition of} \ c_2 () \} \\
= c_1' \theta (\lambda a_1 \to \text{if} \ a_1 \equiv b \text{ then} \lambda q \to \text{FreeEM} (\text{do} \{ l_1 \leftarrow \text{unFreeEM} (k_2' \text{ True} q); l_2 \leftarrow \text{unFreeEM} (k_2' \text{ False} q); \text{return} (l_1 \cup l_2) \}) \text{ else} k_1' a_1)
\]

Let us consider the case \( b = \text{False} \) first, which corresponds to the left distributivity \( p \triangleq (q \cap r) \). Setting \( b = \text{False} \) and expanding \( c_1' \theta \), the last equation becomes

\[
\lambda q \to k_1' \text{ True} (\lambda d_1 \to \text{FreeEM} (\text{do} \{ l_1 \leftarrow \text{unFreeEM} (k_2' \text{ True} (\lambda d_2 \to q (d_1 +_\theta d_2))); l_2 \leftarrow \text{unFreeEM} (k_2' \text{ False} (\lambda d_2 \to q (d_1 +_\theta d_2))); \text{return} (l_1 \cup l_2) \}))
\]

Now from the right-hand side of (28), we calculate:

\[
\lambda q \to c_2 () (\lambda a_2 \to c_1' \theta (\lambda a_1 \to \text{if} \ a_1 \equiv b \text{ else} k_1' a_1)) q \\
\text{let definition of} \ c_2 () \}
\]

\[
\lambda q \to c_2 () (\lambda a_2 \to k_1' \text{ True} (\lambda d_1 \to k_2' a_2 (\lambda d_2 \to q (d_1 +_\theta d_2)))) \\
\text{let definition of} \ c_2 () \}
\]

\[
\lambda q \to \text{FreeEM} (\text{do} \ l_1 \leftarrow \text{unFreeEM} (k_1' \text{ True} (\lambda d_1 \to k_2' \text{ True} (\lambda d_2 \to q (d_1 +_\theta d_2)))); l_2 \leftarrow \text{unFreeEM} (k_1' \text{ False} (\lambda d_1 \to k_2' \text{ False} (\lambda d_2 \to q (d_1 +_\theta d_2)))); \text{return} (l_1 \cup l_2))
\]

It is not difficult to see (29) \( \neq \) (30) for arbitrary monad \( m \) in general, which matches our intuition: under \( ndetH \circ \text{probH} \), computation \( p \triangleq (q \cap r) \) executes \( p \) once but \( (p \triangleq q) \cap (p \triangleq r) \) executes \( p \) twice. Thus \( ndetH \circ \text{probH} \) is not a correct open handler of \( \text{Prob}\NDet \), but is it a correct closed handler of \( \text{Prob}\NDet \)? When \( m \) is the identity monad \( \text{Free Empty} \), the \text{do}-notations in (29) and (30) degenerate to let-bindings, and (29) \( = \) (30) is equivalent to

\[
\lambda q \to k_1' \text{ True} (\lambda d_1 \to k_2' \text{ True} (\lambda d_2 \to q (d_1 +_\theta d_2))) \\
\text{let} \ l_1 = k_1' \text{ True} (\lambda d_2 \to q (d_1 +_\theta d_2)) = \ l_2 = k_1' \text{ True} (\lambda d_1 \to k_2' \text{ True} (\lambda d_2 \to q (d_1 +_\theta d_2))) \\
\text{in} \ l_1 \cup l_2
\]

where \( k_1' , k_2' : \text{Bool} \to (\text{Dist}\ A \to \text{Set} (\text{Dist}\ A)) \to \text{Set} (\text{Dist}\ A) \). However, (31) still does not hold in general. Thus our attempt with Corollary 7.2 seems inconclusive.

However, with a closer look we notice that the functions \( k_1' \) and \( k_2' \) bear some properties not manifested in their types: they correspond to handled subterms of the computation, and therefore they must be built from \( \text{gen} (ndetH \circ \text{probH}) \) and \( \text{alg} (ndetH \circ \text{probH}) \). Indeed, if \( f : (\text{Dist}\ A \to \text{Set} (\text{Dist}\ A)) \to \text{Set} (\text{Dist}\ A) \) is built from \( \text{gen} (ndetH \circ \text{probH}) \) and \( \text{alg} (ndetH \circ \text{probH}) \), then it satisfies

\[
f (\lambda x \to g x \cup h x) = f (g \cup f h) \quad \text{(32)}
\]

and (32) for \( f = k_1' \text{ True} \) implies (31).
7.2 Generalising the Continuation Monad

Note that $\mathsf{Set}(\mathsf{Distr} \ A)$ with join operation $\cup$ is a semi-lattice, and for any set $X$, functions $X \to \mathsf{Set}(\mathsf{Distr} \ A)$ can be equipped with a semi-lattice structure with the join operation defined pointwise: for any $g, h :: X \to \mathsf{Set}(\mathsf{Distr} \ A)$,

$$g \cup h = \lambda x \to g \ x \cup h \ x$$

Then (32) states that $f$ is a join-preserving mapping, i.e. an arrow in the category $\mathsf{SL}$ of semi-lattice. It is a standard result in category theory that there is an adjunctive bijection for any semi-lattices $A, B$, and set $X$

$$\mathsf{SL}(B^X, A) \cong \mathsf{Set}(X, \mathsf{SL}(A, B))$$

where $\mathsf{SL}(B^X, A)$ is the set of join-preserving functions from semi-lattice $A$ to $B^X$ and $\mathsf{SL}(A, B)$ is the set of of join-preserving functions from $A$ to $B$, and $\mathsf{Set}(X, Y)$ is the set of functions from $X$ to $Y$ for any $X$ and $Y$. Consequently, this adjunction gives rise to a monad on $\mathsf{Set}$ mapping $X$ to the set $\mathsf{SL}(B^X, B)$ for any semi-lattice $B$. Then replacing $\mathsf{Cont}$ in the construction of $\mathsf{Fuse}$ in Theorem 5.2 with this monad will allow us to prove (31) and thus $\mathsf{ndetH} \diamond \mathsf{probH}$ is a correct closed handler of the theory $\mathsf{Prob} \bowtie \mathsf{NDet}$ of combined choice.

More generally, for any category $C$ with powers [Mac Lane 1998, p.70], there is an adjunction

$$C^\mathsf{op}(B^X, A) \cong \mathsf{Set}(X, C(A, B))$$

and monad $X \mapsto C(B^X, B)$ for every object $B$ in $C$ [Hinze 2012]. When $C$ is $\mathsf{Set}$, it is exactly the continuation monad. Some other instances are studied in the context of categorical semantics of predicate transformers [Hino et al. 2016; Jacobs 2017]. Similar to the situation of combined choice where we need $C = \mathsf{SL}$, in some applications we may need to choose appropriate $C$ to reflect the invariants in the handled computations that are preserved by the clauses of the handler to prove the correctness of composite handlers.

In summary, in this section we have explored showing the correctness of $\mathsf{ndetH} \diamond \mathsf{probH}$ with respect to the distributive tensor $\mathsf{Prob} \bowtie \mathsf{NDet}$, and it turns out that our technique (Theorem 7.1) is not powerful enough to do so. As we analysed above, this limitation is caused by the fact that some application-specific invariants are lost in the types, which can be overcome by replacing the continuation monad used in Theorem 5.2 with a generalised form. Although we see no substantial difficulty in doing so, we leave adapting the theorems in this paper to the generalised form and a systematic study of interesting examples needing this generalisation as future work.

8 RELATED WORK

**Combinations of Effects.** Hyland et al. [2006] study the sum and tensor of computational effects and show that the sum with the theory of exceptions and interactive IO, and the tensor with mutable state lead to the corresponding monad transformers, and later Cheung [2017] follows this line of research and studies the distributive tensor of effect theories, in particular, the connection with the distributive laws of monads and the example of combining nondeterminism and probabilistic choice. Their work gives a unified account of modularity for computational effects and our work aims to connect this modularity with the modularity of handlers.

**Effect Handlers.** In the original work on effect handlers [Plotkin and Pretnar 2009, 2013], a global effect theory is assumed throughout the language. To avoid the interdependence of typing handlers and proving them correct, Plotkin and Pretnar [2009] provide two calculi (one for defining handlers and one for using them) and, accordingly, two equational logics extending the logic by Plotkin and Pretnar [2008] (one for proving handlers correct and the other for reasoning about computations using handlers). The later work [Plotkin and Pretnar 2013] adopts a simpler approach...
by leaving semantics of incorrect (though well-typed) handlers undefined. In comparison, in this paper handlers interpret signatures instead of theories, so correctness respecting theories becomes an extrinsic property of handlers.

Because many practically useful handlers do not respect the standard theories of their effects and fundamentally the correctness of handlers is undecidable [Plotkin and Pretnar 2013], most later work (with the exceptions [Ahman 2017; Kiselyov et al. 2021; Lukšič and Pretnar 2020]) on effect handlers only considers effect theories with no equations, resulting in fewer reasoning principles for algebraic effects and consequently weaker guarantee of correctness.

Ahman [2017] presents a dependently typed language in which handlers (and proofs showing their satisfaction of the equations of the theory) are represented as user-defined algebra types and applying handlers is done using sequential composition. With the power of dependent types, Ahman [2017] uses handlers to define predicates on effectful computations.

Lukšič and Pretnar [2020] present a type system in which computation types are tagged with a set of equations expected to hold, and the type system is parameterised by a reasoning logic that allows the programmer to actually prove that the equations are respected by a handler. Typical choices of the reasoning logic are those in [Plotkin and Pretnar 2008; Pretnar 2010]. In comparison, our paper is more about techniques for reducing the actual proof work of the correctness of composite handlers, and less about formalising languages and logics in which the proof can be done. However, the semi-formal way of working with equations used in our paper aligns well with Lukšič and Pretnar [2020]’s formalisms: computations are interpreted by free monads ignoring the equations, and equations are separately interpreted as a relation. Thus the systems in [Lukšič and Pretnar 2020] suits well for formalising our results, which is an important piece of future work.

Kiselyov et al. [2021] advocate a different philosophy about the relationship between equations and handlers—they advocate that equations should be distilled from handlers rather than specify handlers a priori. They also study the equations respected by the handlers of state, nondeterminism and their composites. However, from either viewpoint, the eventual proof obligation is the same—an equation is respected by a handler. Thus the results developed in this paper for proving a composite handler respecting some equation are applicable in their setting too. They also emphasise that equational laws should be term congruences under a handler, which is reflected by the \textit{Cong} rule in our definition of equivalent computations \(\sim_T\) (Definition 3.1). Our restriction of modularity is reminiscent of the restriction in [Kiselyov et al. 2021] that operations must be uniquely handled by the concerned handler in their formulation of \textit{equivalence modulo handlers}.

Zhang and Myers [2019] present an operational semantics for a language with effect polymorphism based on \textit{tunneling} in which the parametricity theorem holds for effect-polymorphic functions. In comparison, we have focused exclusively on denotational semantics of effect handlers (presented in Haskell), and we achieve effect polymorphism by being polymorphic in the signature functors, utilising the polymorphic mechanisms of Haskell. Since our technique of handler fusion crucially relies on parametricity, we expect our results to hold only in an operational semantics admitting the parametricity theorem, such as Zhang and Myers [2019]’s and Brachthäuser et al. [2020]’s. Otherwise, a handler may accidentally intercept operations supposed to be handled by other handlers, breaking the modularity of handlers.

Schrijvers et al. [2019] introduce \textit{modular handlers} that play an essential role in this paper. They also compare modular handlers to monad transformers, showing that the expressibility of modular handlers and monad transformers implementing only algebraic operations are equivalent in Haskell. However, the equal expressibility crucially depends on the features present in the language, as demonstrated by Forster et al. [2017] that there is no type-preserving translation from effect handlers to layered monads [Filinski 1999] in a call-by-push-value calculus \textit{without} polymorphism and inductive types. In [Schrijvers et al. 2019], equations of algebraic theories are
not considered, which we recover in this paper. We also formalise notions of the correctness of modular handlers and study the correctness of composite modular handlers using handler fusion.

Xie et al. [2020] introduce the scoped-resumption restriction on handlers to simplify reasoning and aid optimisation, while we impose the modular restriction for a similar purpose. Indeed, their non-scoped example in [Xie et al. 2020, Section 2.2] can be rejected by the modular restriction too. However, they check scoped resumptions dynamically, whereas modular handlers are statically typed. It is interesting future work to establish the relationship between these two restrictions.

Hillerström and Lindley [2018] introduce shallow handlers that semantically corresponds to case-splits on syntax trees of computations, whereas traditional deep handlers correspond to catamorphisms. When used with general recursion, shallow handlers can conveniently implement handling schemes that do not fit in the structure of deep handlers, such as handling two mutually dependent programs. However, this is at the cost of relinquishing structural recursion inherent in deep handlers that offers the programmer more reasoning principles. In particular, we have shown how the fusion property can be used to reason about composites of deep handlers.

The techniques developed in this paper only apply to modular handlers. However, not all handlers in the various languages discussed above are modular. A rough criterion is that a handler is modular as long as it does not use its resumption in any way other than invoking it. In particular, it cannot apply the handling construct on its resumption. For languages implementing effect polymorphism such as KöKA [Leijen 2017], this condition is a consequence of a handler being polymorphic in unhandled operations. For languages without effect polymorphism such as those in [Bauer and Pretnar 2014; Plotkin and Pretnar 2009], this is not automatically guaranteed. Appendix F shows a fine-grained call-by-value calculus of handlers in which all handlers must be modular. Although most handlers appearing in the literature are modular, there is an example of non-modular handlers of mutable state by handling the get operation in the clause of put operation in [Biernacki et al. 2017, page 4]. We leave extending our work to non-modular handlers as future work.

**CPS Transformations.** There is a lot of work on using CPS transformations to optimise effectful programs. Here we discuss some typical ones in the context of algebraic effects and handlers and compare them with the transformation that we use for fusing handlers.

Voigtländer [2008] shows that CPS transformation of free monads with the codensity monad gives an asymptotic improvement on the time complexity of monadic binding operations. Kammar et al. [2013] use CPS transformations based on the codensity and continuation monads in their implementations of effect handlers, in which the continuation monad is iterated to allow the operations in a computation to be handled by different open handlers, a concept that we borrow and use in this paper. Schuster et al. [2020] translate effectful programs written in capability-passing style into iterated continuation passing style. They also statically specialise the abstract capabilities in a CPS translated program to corresponding concrete handlers by translating to a two-stage simply typed lambda calculus, and thus eliminate all handling constructs in the translation result.

Compared to these works that apply CPS transformations to computations for performance improvement, this paper uses CPS transformation on handlers instead of computations, and the purpose is mostly for reasoning about handlers. Despite different motivations, the techniques of CPS transformation are similar, and we believe that it is possible to devise a handling-eliminating translation similar to the one given in [Schuster et al. 2020] if we iteratively fuse all handlers using our fusion combinator and inline the resulting all-in-one handler into a computation.

Our handler fusion is directly inspired by the work by Wu and Schrijvers [2015] with the minor difference that we use the continuation monad instead of the codensity monad for CPS transformation, and they rely on the compiler to perform static fusion, whereas our fusion combinator explicitly gives the result of fusion when the handlers are defined in the form of modular handlers.
Similar fusion technique is also used by Seynaeve et al. [2020] to eliminate intermediate lists when implementing nondeterminism with mutable state.

**Proof Assistants for Equational Reasoning.** The results of this paper allow the programmer to prove the correctness of composite handlers by doing equational reasoning about the clauses of handlers. However, all the proofs, both of our theorems and the use cases of the theorems, in this paper are done in a paper-and-pencil style. Thus we expect that the proposed technique would be more usable for programmers if there are mechanised tools for equational reasoning about programs when applying the proposed technique. This can be possibly achieved by resorting to existing proof assistants supporting equational reasoning about Haskell programs. Among them, LiquidHaskell [Vazou et al. 2018, 2017] seems promising, since it utilises SMT solvers to automatically verify the equality of programs. Another option is converting Haskell programs to Coq using the tools by Breitner et al. [2018]; Spector-Zabusky et al. [2018] and doing equational reasoning therein (with libraries like [Tesson et al. 2011] that aid with equational reasoning). Beyond formalising equational reasoning about handlers, a complete mechanised formalisation of the theorems in the paper is also an interesting piece of future work.

9 CONCLUSION

This paper has studied a way to reason about the semantics of sequentially composed handlers by fusing them into one, which allows us to derive relatively simple conditions for the semantics of the composite handler to agree with any combination of the effect theories separately handled. With this connection between modular specifications (effect theories) of effects and modular implementations (handlers) of effects, programmers are furnished with a principled way to determine the right order of composing handlers for their need by equational reasoning, as demonstrated in several case studies. The following directions can be explored in the future:

- We wish to find a concise categorical formulation of modular carriers and handlers, so that the techniques in this paper can be generalised to categories other than the category of sets.
- Our equational proofs in this paper are done in a paper-and-pencil way. It will be useful to find a way to formalise them with reasonable effort and even automate them.
- As demonstrated in Section 7.2, the continuation monad used for fusion needs to be generalised in some cases. We wish to find more examples of this and make a systematic study.
- The fusion combinator of modular handlers can possibly be used to implement a compiler of effect handlers that fuses all handlers that can be determined at compile time and inline them into computations.
- We have only considered algebraic operations and we wish to extend this techniques in the paper to a broader family such as scoped operations [Piróg et al. 2018].

Effect handlers have proven to be a powerful construct for modelling language features modularly, but a powerful construct is only useful when powerful reasoning techniques are available. We hope that this paper can inspire more reasoning techniques for handlers to be developed in the future.

A  EQUATIONS IN CHURCH ENCODINGS

In the appendices, we switch to work with equations based on Church encodings, which are equivalent to the definition of equations Section 2.1 but simply the proofs.

Definition A.1 (Equations in Chuch encodings). Given a signature $\Sigma$, types $\Gamma$ and $v$, an equation in Church encodings for $\Sigma$ with free value variables $\Gamma$ and free computation variables $v$ is a pair of templates:

$$\text{data } Equation_C \Sigma \Gamma v = Eqn_C (Template \Sigma \Gamma v) (Template \Sigma \Gamma v)$$

$$\text{type } Template \Sigma \Gamma v = \forall c. (\Sigma c \rightarrow c) \rightarrow (v \rightarrow c) \rightarrow c$$

Moreover, we say that an algebra $alg: \Sigma c \rightarrow c$ respects an equation $(Eqn_C lhs rhs): Equation_C \Sigma \Gamma v$ if for any $t :: \Gamma$ and $k :: v \rightarrow c$,

$$lhs alg t k = rhs alg t k$$

Lemma A.1. There is an isomorphism between equations based on free monads (11) and equations based on Church encodings.

$$\phi :: \text{Functor } \Sigma \Rightarrow Equation \Sigma \Gamma v \rightarrow Equation_C \Sigma \Gamma v$$

Moreover, an algebra $alg$ respects an equation in Church encodings if and only if it respects the isomorphic equation in free monads (Definition 2.1).

Proof. The isomorphism can defined as follows:

$$\phi (l \doteq r) = Eqn_C (\lambda alg t k \rightarrow fold alg k (l t)) (\lambda alg t k \rightarrow fold alg k (r t))$$

and its inverse is

$$\phi^\circ :: \text{Functor } \Sigma \Rightarrow Equation_C \Sigma \Gamma v \rightarrow Equation \Sigma \Gamma v$$

$$\phi^\circ (Eqn_C l r) = (\lambda t \rightarrow l \text{ Op } t \text{ Var}) \doteq (\lambda t \rightarrow r \text{ Op } t \text{ Var})$$

We refer the reader to [Hinze 2005] for the proof that $\phi$ and $\phi^\circ$ form a pair of isomorphism. An algebra respects an equation in Church encodings iff it respects the isomorphic equation in free monads following the definitions of equation respecting and $\phi$. □

B  PROOF OF HANDLER FUSION

In this section we prove Theorem 5.3. The technique is essentially the same as the one in [Wu and Schrijvers 2015], although the setting in their paper is slightly different from the setting of modular handlers used in this paper.

Definition B.1. For convenience in our calculation, we divide $\text{handle}$ in Definition 3.3 into the following smaller functions:

$$\text{split} :: (\Sigma_1 c \rightarrow c) \rightarrow (\Sigma_2 c \rightarrow c) \rightarrow (\Sigma_1 + \Sigma_2) c \rightarrow c$$

$$\text{openAlg} :: (\text{Functor } sig', \text{MCarrier } c) \Rightarrow \text{MHandler } \Sigma c a b$$

$$\text{split alg}_1 alg_2 (\text{Inl } x) = alg_1 x$$

$$\text{split alg}_1 alg_2 (\text{Inr } x) = alg_2 x$$

$$\text{openAlg } h = \text{split } (alg) \text{ forward}$$

It it clear that

$$\text{handle } h = \text{run } h \cdot \text{fold } (\text{openAlg } h) (\text{gen } h)$$

(33)
B.1 Fold/Build fusion for free

The underlying technique for our proof is fold/build fusion for free introduced by [Hinze et al. 2011]. In this subsection, we state it in our context of free monads (Theorem B.1) and establish relevant prerequisites (mainly Lemma B.5) to apply the free theorem.

Definition B.2. We say that a monad \( M \) is a term monad of signature \( \Sigma \) if there is a parametric family of \( \Sigma \)-algebras \( \text{con} :: \forall a. \Sigma (M a) \rightarrow M a \):

\[
\text{class} \ (\text{Monad } m, \text{Functor } \Sigma) \Rightarrow \text{TermMonad } m \Sigma \text{ where } \\
\text{con} :: \Sigma (m a) \rightarrow m a
\]

with the algebraicity law:

\[
\text{con} \circ \text{op} \gg k = \text{con} \circ (\text{fmap} \ (\gg k) \circ \text{op})
\]

Definition B.3. Given two term monads \( M_1 \) and \( M_2 \) of the same signature \( \Sigma \), a term monad morphism from \( M_1 \) to \( M_2 \) is a monad morphism \( f :: \forall a. M_1 a \rightarrow M_2 a \) from \( M_1 \) to \( M_2 \) that is simultaneously a \( \Sigma \)-algebra homomorphism from \( \text{con}_{M_1} \) to \( \text{con}_{M_2} \) for any \( a \).

The parametricity of polymorphic functions entails the following property.

Theorem B.1 (Fusion for Free). For any function \( g :: \text{TermMonad } m \Sigma \Rightarrow X \rightarrow m Y \), term monads \( M_1 \) and \( M_2 \) of \( \Sigma \), and term monad morphism \( f :: M_1 a \rightarrow M_2 a \) from \( M_1 \) to \( M_2 \), the following diagram commutes:

\[
\begin{array}{ccc}
X & \xrightarrow{g_{M_1}} & M_1 Y \\
\downarrow{g_{M_2}} & & \downarrow{f_Y} \\
M_2 Y & & 
\end{array}
\]

where subscripts are type applications of polymorphic functions.

Lemma B.2. Monad \( \text{Free } \Sigma \) is a term monad of \( \Sigma \) for any functor \( \Sigma \):

\[
\text{instance Functor } \Sigma \Rightarrow \text{TermMonad } (\text{Free } \Sigma) \Sigma \text{ where con = Op}
\]

Proof. As shown in Section 2, \( \text{Free } \Sigma \) is a monad and its \( \gg \) implementation directly entails algebraicity. \( \square \)

Remark B.1. In fact, \( \text{Free } \Sigma \) is the initial term monad of \( \Sigma \): for any term monad \( m \) of \( \Sigma \), there is exactly one term monad morphism from \( \text{Free } \Sigma \) to \( m \).

Lemma B.3. For any type \( c \) carrying a \( \Sigma \)-algebra \( \text{alg} :: \Sigma c \rightarrow c \), monad \( \text{Cont}_c \) is a term monad of \( \Sigma \) with \( \text{con} = \text{liftAlgCont } \text{alg} \) where \( \text{liftAlgCont} \) (17) is defined in Section 5.

Proof. \( \text{Cont}_C \) is clearly a monad. What remains is to show that \( \text{con} \) satisfies algebraicity:

\[
\text{con} \circ \text{op} \gg k = \{
\text{\small \begin{array}{l}
\text{Expanding con }\\
\text{liftAlgCont alg op} \gg k
\end{array}}\}
\]

\[
= \{
\text{\small \begin{array}{l}
\text{Expanding liftAlgCont (17)}
\end{array}}\}
\]

\[
\text{Cont (}\lambda q \rightarrow \text{alg (fmap (}\lambda m \rightarrow \text{runCont m q) op)) \gg k
\]

\[
= \{
\text{\small \begin{array}{l}
\text{Expanding} \gg \text{ and letting } m = \text{Cont (}\lambda q \rightarrow \text{alg (fmap (}\lambda n \rightarrow \text{runCont n q) op))}
\end{array}}\}
\]

\[
\text{Cont (}\lambda t \rightarrow \text{runCont m (}\lambda x \rightarrow \text{runCont (}k x) t))
\]

\[
= \{
\text{\small \begin{array}{l}
\text{Expanding runCont m}
\end{array}}\}
\]

\[
\text{Cont (}\lambda t \rightarrow (\lambda q \rightarrow \text{alg (fmap (}\lambda n \rightarrow \text{runCont n q) op)) (}\lambda x \rightarrow \text{runCont (}k x) t))
\]
To apply Theorem B.1 to fuse

It is clear that

Given

Lemma B.6.

and de Moor 1997; Hinze 2013.

from monad morphism followed by something else.

\[ \Sigma \text{term monad of} \]

it can be shown that it is also a monad morphism.

By the definition of

Proof.

Because \( \text{openAlg} \ h_2 \) have type \((\Sigma_2 + \text{sig'}) \rightarrow (C_2 \ (\text{Free} \ \text{sig'})) \rightarrow C_2 \ (\text{Free} \ \text{sig'})\), by Lemma B.3, \( \text{Cont}_{C_2} \ (\text{Free} \ \text{sig'}) \) is a term monad of \( \Sigma_2 + \text{sig'} \).

Lemma B.4. Given a modular handler \( h_2 :: \text{MHandler} \ \Sigma_2 \ C_2 \ Y \ Z \), then for any signature \( \text{sig'} \), \( \text{Cont}_{C_2} \ (\text{Free} \ \text{sig'}) \) is a term monad of \( \Sigma_2 + \text{sig'} \) with

\[ \text{con}_{\text{CPS}} = \text{liftAlgCont} \ (\text{openAlg} \ h_2) \]

Proof. Because \( \text{openAlg} \ h_2 \) have type \((\Sigma_2 + \text{sig'}) \rightarrow (C_2 \ (\text{Free} \ \text{sig'})) \rightarrow C_2 \ (\text{Free} \ \text{sig'})\), by Lemma B.3, \( \text{Cont}_{C_2} \ (\text{Free} \ \text{sig'}) \) is a term monad of \( \Sigma_2 + \text{sig'} \).

Lemma B.5. Given the data as in the last lemma, \( \text{fold} \ \text{con}_{\text{CPS}} \ \text{return}_{\text{Cont}} \) is a term monad morphism from \( \text{Free} \ (\Sigma_2 + \text{sig'}) \) to \( \text{Cont}_{C_2} \ (\text{Free} \ \text{sig'}) \).

Proof. By the definition of \( \text{fold} \), it is clearly a \((\Sigma_2 + \text{sig'})\)-homomorphism. With some calculation, it can be shown that it is also a monad morphism.

B.2 Handle with Term Monads

To apply Theorem B.1 to fuse \( h_2 \cdot \text{handle} \ h_1 \), we need (i) \( \text{handle} \ h_1 \) to operate on a parametric term monad of \( \Sigma_2 + \text{Sig'} \) instead of just \( \text{Free} \ (\Sigma_2 + \text{Sig'}) \), and (ii) \( \text{handle} \ h_2 \) to be factored as a term monad morphism followed by something else.

For the first requirement, we define the following generalised version of \( \text{handle} \):

\[ \text{ghandle} :: (\text{MCarrier} \ c, \text{Functor} \ \Sigma, \text{Functor} \ \text{sig'}, \text{TermMonad} \ m \ \text{sig'}) \]

\[ \Rightarrow \text{MHandler} \ \Sigma \ c \ a \ b \rightarrow \text{Free} \ (\Sigma + \text{sig'}) \ a \rightarrow m \ b \]

\[ \text{ghandle} \ h = \text{run} \ h \cdot \text{fold} \ (\text{gopenAlg} \ h) \ (\text{gen} \ h) \]

\[ \text{gopenAlg} :: (\text{Functor} \ \text{sig'}, \text{MCarrier} \ c, \text{TermMonad} \ m \ \text{sig'}) \]

\[ \Rightarrow \text{MHandler} \ \Sigma \ c \ a \ b \rightarrow (\Sigma + \text{sig'}) \ (c \ m) \rightarrow c \ m \]

\[ \text{gopenAlg} \ h = \text{split} \ (\text{alg} \ h) \ (\text{fwd} \cdot \text{con} \cdot \text{fmap} \ \text{return}) \]

It is clear that

\[ (\text{ghandle} \ h_1)_{\text{Free} \ \text{sig'}} = \text{handle} \ h_1 \] \hspace{1cm} \text{(35)}

Then for the second requirement, we have the following lemma.

Lemma B.6. Given \( h_2 :: \text{MHandler} \ \Sigma_2 \ C_2 \ Y \ Z \), it is the case that

\[ \text{fold} \ (\text{openAlg} \ h_2) \ (\text{gen} \ h_2) = (\lambda x \rightarrow \text{run} \ x \ (\text{gen} \ h_2)) \cdot \text{fold} \ \text{con}_{\text{CPS}} \ \text{return}_{\text{Cont}} \]

Proof. It can be checked that \( (\lambda x \rightarrow \text{run} \ x \ (\text{gen} \ h_2)) \) is a \((\Sigma_2 + \text{sig'})\)-algebra homomorphism from \( \text{con}_{\text{CPS}} \) to \( \text{openAlg} \ h_2 \), and then the equation can be shown by an ordinary fold fusion [Bird and de Moor 1997; Hinze 2013].
Now we can use Theorem B.1 to fuse the folds of the two handlers:

\[
\text{handle } h_2 \cdot \text{handle } h_1 = \{ \text{Equation 33} \} \\
\text{run } h_2 \cdot \text{fold } (\text{openAlg } h_2) (\text{gen } h_2) \cdot \text{handle } h_1 = \{ \text{Equation 35} \} \\
\text{run } h_2 \cdot (\lambda x \rightarrow \text{runCont } x (\text{gen } h_2)) \cdot \text{fold } (\text{openAlg } h_2) (\text{gen } h_2) \cdot (\text{ghandle } h_1)_{\text{Free } (\Sigma_2 + \text{sig}')} = \{ \text{Lemma B.6} \} \\
\text{run } h_2 \cdot (\lambda x \rightarrow \text{runCont } x (\text{gen } h_2)) \cdot (\text{ghandle } h_1)_{\text{Cont}_C (\text{Free sig}')} \\
\text{Now we calculate from the side of handle } (h_2 \circ h_1): \\
\text{handle } (h_2 \circ h_1) = \text{run } ((h_2 \circ h_1) \cdot \text{fold } (\text{openAlg } h_2) (\text{gen } h_2)) = \text{run } h_2 \cdot (\lambda x \rightarrow \text{runCont } x (\text{gen } h_2)) \cdot \text{run } h_1 \cdot \text{fold } (\text{openAlg } h_2) (\text{gen } h_2) = \text{run } h_2 \cdot (\lambda x \rightarrow \text{runCont } x (\text{gen } h_2)) \cdot \text{run } (h_1 \circ h_1) \cdot \text{fold } (\text{openAlg } h_2) (\text{gen } h_2)
\]

(we omit constructors and destructors Fuse and unFuse for clarity). To complete the proof of handle $h_2 \cdot \text{handle } h_1 = \text{handle } (h_2 \circ h_1) \cdot \text{assoc}^\circ$, it is sufficient to show

\[
(\text{ghandle } h_1)_{\text{Cont}_C (\text{Free sig}')} = \text{run } h_1 \cdot \text{fold } (\text{openAlg } h_2) (\text{gen } h_1) \cdot \text{assoc}^\circ 
\]

By definition of ghandle,

\[
(\text{ghandle } h_1)_{\text{Cont}_C (\text{Free sig}')} = \text{run } h \cdot \text{fold } (\text{gopenAlg } h_1)_{\text{gen } h} (\text{Cont}_C (\text{Free sig'}))
\]

Thus it is sufficient to show

\[
\text{fold } (\text{gopenAlg } h_1)_{\text{gen } h} (\text{Cont}_C (\text{Free sig}')) = \text{fold } (\text{openAlg } (h_2 \circ h_1)) (\text{gen } h_1) \cdot \text{assoc}^\circ 
\]

Lemma B.7. Let $\phi : (\Sigma_1 + (\Sigma_2 + \text{sig}'')) \rightarrow ((\Sigma_1 + \Sigma_2 + \text{sig}')) a \circ b$ be the evident isomorphism between these two signatures. We have

\[
(\text{gopenAlg } h_1)_{\text{Cont}_C (\text{Free sig}')} = (\text{openAlg } (h_2 \circ h_1)) \cdot \phi
\]

Proof. By case analysis on input $x$,

Case B.7.1. If $x = \text{Inl } c$,

\[
(\text{gopenAlg } h_1)_{\text{Cont}_C (\text{Free sig}')} (\text{Inl } c) = \text{alg } h_1 c = \text{openAlg } (h_2 \circ h_1) (\phi (\text{Inl } c))
\]

Case B.7.2. If $x = \text{Inr } (\text{Inl } c)$,

\[
(\text{gopenAlg } h_1)_{\text{Cont}_C (\text{Free sig}')} (\text{Inr } (\text{Inl } c)) = \{ \text{definition of gopenAlg } \} \\
(\text{fwd } \cdot \text{con}_{\text{CPS}} \cdot \text{fmap return}) (\text{Inl } c) = \{ \text{definition of con}_{\text{CPS}} \} \\
(\text{fwd } \cdot \text{liftAlgCont } (\text{openAlg } h_2)) \cdot \text{fmap return} (\text{Inl } c) = \{ \text{fmap on Inl } \} \\
(\text{fwd } \cdot \text{liftAlgCont } (\text{openAlg } h_2)) (\text{Inl } (\text{fmap return } c)) = \{ \text{definition of liftAlgCont } \}
\]
\[
\text{fwd } (\text{cont } (\lambda k \rightarrow \text{openAlg } h_2 ((\text{fmap } (\lambda m \rightarrow \text{runCont } m k) \cdot \text{return}) c))) = \\
\quad \{\downarrow \text{fmap on Inl}\} \\
\text{fwd } (\text{cont } (\lambda k \rightarrow \text{openAlg } h_2 ((\text{fmap } ((\lambda m \rightarrow \text{runCont } m k) \cdot \text{return}) c)))) = \\
\quad \{\downarrow \text{definition openAlg } h_2 \text{ on Inl}\} \\
\text{fwd } (\text{cont } (\lambda k \rightarrow \text{alg } h_2 ((\text{fmap } ((\lambda m \rightarrow \text{runCont } m k) \cdot \text{return}) c))) = \\
\quad \{\downarrow \text{cancelling return and runCont}\} \\
\text{fwd } (\text{cont } (\lambda k \rightarrow \text{alg } h_2 ((\text{fmap } ((\lambda m \rightarrow \text{runCont } m k) \cdot \text{return}) c))) = \\
\quad \{\uparrow \text{definition of liftAlgCont}\} \\
(\text{fwd} \cdot \text{liftAlgCont } (\text{alg } h_2) \cdot \text{fmap return}) c \\
= \{\uparrow \text{definition of } \circ\} \\
\text{alg } (h_2 \circ h_1) \ (\text{Inr } c) \\
= \{\uparrow \text{definition of openAlg}\} \\
\text{openAlg } (h_2 \circ h_1) \ (\text{Inl } (\text{Inr } c)) \\
= \{\uparrow \text{definition of } \phi\} \\
\text{openAlg } (h_2 \circ h_1) \ (\phi \ (\text{Inr } (\text{Inl } c)))
\]

Case B.7.3. If \(x = \text{Inr } (\text{Inr } c)\),
\[
(\text{openAlg } h_1)_{\text{Cont}_{C_2} (\text{free sig}')} \ (\text{Inr } (\text{Inr } c)) = \\
\quad \{\downarrow \text{definition of openAlg}\} \\
(\text{fwd} \cdot \text{con}_{\text{CPS}} \cdot \text{fmap return}) \ (\text{Inr } c) = \\
\quad \{\downarrow \text{definition of con}_{\text{CPS}}\} \\
(\text{fwd} \cdot (\text{liftAlgCont } (\text{openAlg } h_2)) \cdot \text{fmap return}) \ (\text{Inr } c) = \\
\quad \{\downarrow \text{definition of liftAlgCont}\} \\
(\text{fwd} \cdot (\text{liftAlgCont } (\text{fwd}_{C_2} (\text{Op} \cdot \text{fmap Var})) \cdot \text{fmap return}) c \\
= \{\downarrow \text{definition of liftAlgCont and simplification}\} \\
\text{fwd } (\text{cont } (\lambda k \rightarrow (\text{fwd}_{C_2} (\text{Op} \cdot \text{fmap } (\lambda x \rightarrow \text{Var } (k x))) \ (\text{Inr } c)))) \\
= \{\uparrow \text{fmap k } \cdot \text{Var} = (\lambda x \rightarrow \text{Var } (k x))\} \\
\text{fwd}_{C_1} (\text{cont } (\lambda k \rightarrow \text{fwd}_{C_2} (\text{Op} \cdot \text{fmap } (\lambda x \rightarrow \text{Var } (k x)))))) = \\
\quad \{\uparrow \text{fmap preserves function composition}\} \\
\text{fwd}_{C_1} (\text{cont } (\lambda k \rightarrow \text{fwd}_{C_2} (\text{Op} \cdot \text{fmap } (\lambda x \rightarrow \text{Var } (k x)))))) = \\
\quad \{\uparrow \text{fmap on Op}\} \\
\text{fwd}_{C_1} (\text{cont } (\lambda k \rightarrow \text{fwd}_{C_2} (\text{fmap k } \cdot \text{Var} (\text{fmap Var c))))) = \\
\quad \{\uparrow \text{definition of reflect}_{\text{EM}}\} \\
(\text{fwd}_{C_1} \cdot \text{reflect}_{\text{EM}} \cdot \text{Op} \cdot \text{fmap Var}) c \\
= \{\uparrow \text{definition of fwd for Fuse}\} \\
(\text{fwd}_{\text{Fuse}} \cdot \text{Op} \cdot \text{fmap Var} ) c \\
= \{\uparrow \text{definition of } h_2 \circ h_1\} \\
\text{openAlg } (h_2 \circ h_1) \ (\text{Inr } c) \\
= \{\uparrow \text{definition of } \phi\} \\
\text{openAlg } (h_2 \circ h_1) \ (\phi \ (\text{Inr } (\text{Inr } c)))
Now Equation 37 follows from this lemma by base functor fusion [Hinze 2013]. This completes our proof of Theorem 5.3.

C CORRECT HANDLERS INDUCE CORRECT TRANSFORMATIONS

This section proves Theorem 4.1. For brevity, we will only prove for open correctness of Theorem 4.1 since the case for closed correctness can be proved by replacing all occurrences of ‘for any $T' :: \text{Theory } \Sigma$’ in the proof with $T'$ being the empty theory. We will use functions defined in Definition B.1, the function $ghandle$, and the concept of term monads (Definition B.2) from the previous section, but the other results from the last section are not used.

Given a theory $T :: \text{Theory } \Sigma$, a model of $T$ is a set $C$ with an algebra $\Sigma_C \to C$ that respects the equations of $T$. It is standard [Bauer 2018; Plotkin and Power 2002] that given any set $X$, the quotient set $(\text{Free } \Sigma X)/\sim_T$ is the free model of $T$ generated by $X$, and that the mapping from $X$ to $(\text{Free } \Sigma X)/\sim_T$ is a monad, which we denote by monad $FM\Sigma$ with

\[
\text{return } x = [\text{Var } x]
\]
\[
[\text{return } x] \gg k = k \cdot x
\]
\[
[\text{Op } op] \gg k = [\text{Op } (\text{fmap } (\gg k) \cdot op)]
\]

where $[\cdot]$ means the equivalence class that an element belongs to, instead of a list. Because $\sim_T$ is defined to be a congruence relation on $\text{Free } \Sigma$ (see Definition 3.1), the above definition of $\gg$ is well defined. $FM\Sigma$ is clearly a term monad (Definition B.2) of $\Sigma$ with $con x = [\text{Op } x]$. The universal property of $FM\Sigma$ says that given any model $(C :: \Sigma, \text{alg } :: \Sigma C \to C)$ and a function $gen :: X \to C$, there is a unique $T$-model homomorphism $\text{fold alg gen}$ from $FM\Sigma X$ to $C$ such that $\text{fold alg gen } [\text{Var } x] = gen x$

Additionally, for any $m :: \text{Free } \Sigma X$,

\[
\text{fold alg gen } [m] = \text{fold alg gen } m
\]  

(39)

**Lemma C.1.** Given a term monad $M$ of $\Sigma$, a modular carrier $C$, define

\[
\text{forward } :: (\text{TermMonad } M \Sigma, \text{MCarrier } C) \Rightarrow \Sigma (C M) \to C M
\]

\[
\text{forward } = \text{fwd } \cdot \text{con } \cdot \text{fmap return}
\]

then $fwd :: M (C M) \to C M$ is a $\Sigma$-algebra homomorphism from $con :: \Sigma (M (C M)) \to M (C M)$ to $\text{forward } :: \Sigma (C M) \to C M$:

\[
\text{fwd } \cdot \text{con } = \text{forward } \cdot \text{fmap } \text{fwd}
\]

**Proof.** First we define $con' :: \forall a. \Sigma a \to M a$ by $con' = con \cdot \text{fmap return}$. Conversely,

\[
con = \{ \uparrow \text{join } \cdot \text{return } = \text{id } \}
\]

\[
con \cdot \text{fmap join } \cdot \text{fmap return}
\]

\[
= \{ \uparrow \text{algebraicity of con } \}
\]

\[
\text{join } \cdot \text{con } \cdot \text{fmap return}
\]

\[
= \text{join } \cdot \text{con'}
\]

Then we calculate

\[
\text{forward } \cdot \text{fmap } \text{fwd}
\]
Lemma C.2. Given a modular carrier $C$, a term monad $M$ of $\Sigma$, if $\text{con}_{M,a}$ respects an equation $\text{lhs} = \text{rhs}$ for any $a$ in the sense of Definition A.1, then the forward function defined in the last lemma respects $\text{lhs} = \text{rhs}$ too.

Proof. For any function $f$ of type 

$$\forall c. (\Sigma \cdot c \rightarrow c) \rightarrow G \rightarrow (V \rightarrow c) \rightarrow c$$

for some $G$ and $V$, if we view $c$ and the first argument $\Sigma \cdot c \rightarrow c$ as a $\Sigma$-algebra, by parametricity [Reynolds 1983; Voigtländer 2009; Wadler 1989] and Lemma C.1, given any $g :: G$ and $k :: V \rightarrow M (C M)$, we have

$$\text{fwd} (f \cdot \text{con} \cdot g \cdot k) = f \cdot \text{forward} \cdot (\text{fwd} \cdot k) \quad (40)$$

Assuming $\text{lhs}$ and $\text{rhs}$ has type Template $G V$, to prove $\text{lhs} \cdot \text{forward} \cdot g \cdot k' = \text{rhs} \cdot \text{forward} \cdot g \cdot k'$ for any $g :: G$ and $k' :: V \rightarrow C M$, we define $k = \text{return} \cdot k'$. By the Eilenberg-Moore property of $\text{fwd}$, we have $k' = \text{fwd} \cdot k$ and we calculate

$$\text{lhs} \cdot \text{forward} \cdot g \cdot k'$$

$$= \text{lhs} \cdot \text{forward} \cdot g \cdot (\text{fwd} \cdot k)$$

$$= \{ \text{Equation 40 for } f := \text{lhs} \}$$

$$\text{fwd} (\text{lhs} \cdot \text{con} \cdot g \cdot k)$$

$$= \{ \text{assumption that } \text{con} \text{ respects } \text{lhs} = \text{rhs} \}$$

$$\text{fwd} (\text{rhs} \cdot \text{con} \cdot g \cdot k)$$

$$= \{ \text{reverse of the previous steps} \}$$

$$\text{rhs} \cdot \text{forward} \cdot g \cdot k'$$

Then we conclude $\text{forward}$ respects the equation $\text{lhs} = \text{rhs}$.

Lemma C.3. Given $h :: M\text{Handler} \Sigma \cdot C \cdot A \cdot B$, if $h$ is a correct open handler of theory $T :: \text{Theory} \Sigma$, then for any $\text{sig}'$ and $T' :: \text{Theory} \Sigma'$, with

$$\text{gopenAlg} \ h :: (\Sigma + \text{sig}') (C (\text{FM sig'})) \rightarrow C (\text{FM sig'})$$

defined as in Section B.2, is a model of $T + T'$.

Proof. Because $h$ is a correct open handler of $T$, $C (\text{FM sig'})$ is a model of $T$ with algebra $\text{alg} \ h$. The monad $\text{FM sig'}$ is a term monad of $\text{sig}'$, so Lemma C.2 implies that $C (\text{FM sig'})$ with algebra $\text{fwd} \cdot \text{con} \cdot \text{fmap return}$ is model of $T'$. By definition, equations of $T + T'$ are either an equation from $T$ or $T'$, and $\text{gopenAlg} \ h$ is exactly $\text{split} \ (\text{alg} \ h) \ (\text{fwd} \cdot \text{con} \cdot \text{fmap return})$. Thus $C (\text{FM sig'})$ is a model of $T + T'$.
Lemma C.4. Given a handler \( h :: \text{MHandler} \Sigma \ C \ A \ B \), two theories \( T :: \text{Theory} \Sigma \) and \( T' :: \text{Theory} \Sigma \), if \( c_1, c_2 :: \text{Free} (\Sigma + \text{sig}') \) \( A \) for some type \( A \) such that \( c_1 \sim_{T+T'} c_2 \), then

\[
\text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}} c_1 = \text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}} c_2
\]

Proof. By Lemma C.3, \( C (\text{FM sig}') \) is a \( (T + T') \)-model with algebra \( (\text{gopenAlg} h)_{\text{FM sig'}} \). Thus by Equation 39, for any \( c :: \text{Free} (\Sigma + \text{sig}') \) \( A \)

\[
\text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}} c = \text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}} [c]
\]

Now that \( c_1 \sim_{T+T'} c_2, [c_1] = [c_2] \). Therefore,

\[
\begin{align*}
\text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}} c_1 \\
= \text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}} [c_2] \\
= \text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}} c_2
\end{align*}
\]

Now we are ready to prove Theorem 4.1 using parametricity [Reynolds 1983; Voigtländer 2009; Wadler 1989]. Let \( h :: \text{MHandler} \Sigma \ C \ A \ B \) be a correct open handler of \( T :: \text{Theory} \Sigma, T' :: \text{Theory} \Sigma \) be any theory, \( c_1, c_2 :: \text{Free} (\Sigma + \text{sig}') \) \( A \) be any two computations such that \( c_1 \sim_{T+T'} c_2 \). Because \( \text{ghandle} \) is polymorphic in its \( \text{TermMonad} \) argument \( m \), and \( \text{[\_]} :: \forall a. \text{Free} \text{ sig'} \ a \to \text{FM sig'} \ a \) is evidently a \( \text{TermMonad} \) morphism, thus by parametricity, for any \( c \),

\[
\text{[\text{ghandle} h_1], \text{Free} \text{ sig'} \ c} = (\text{ghandle} h_1)_{\text{FM sig'}} c
\]

(41)

Then

\[
\begin{align*}
\text{[\text{handle} c_1]}
&= \text{[\text{ghandle} h_1], \text{Free} \text{ sig'} \ c_1} \\
&= (\text{ghandle} h_1)_{\text{FM sig'}} c_1 \\
&= ((\text{run} h)_{\text{FM sig'}} \cdot \text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}}) c_1 \\
&= \{ \text{Lemma C.4} \} \\
&= ((\text{run} h)_{\text{FM sig'}} \cdot \text{fold} (\text{gopenAlg} h)_{\text{FM sig'}} (\text{gen} h)_{\text{FM sig'}}) c_2 \\
&= \{ \text{reverse of the above steps} \} \\
\text{[\text{handle} c_2]
\end{align*}
\]

Then by definition \([\text{handle} c_1] = [\text{handle} c_2]\) iff. \(\text{handle} c_1 \sim_T \text{handle} c_2\), which is what we want to show.

D PROOFS OF PRESERVATION OF EQUATIONS

This section contains detailed calculations to prove Theorem 5.5.

Lemma D.1. For any functor \( \Sigma \), types \( \Gamma, V \), function \( f :: \forall c. (\Sigma \ c \to c) \to \Gamma \to (V \to c) \to c \), function \( \text{alg} :: \Sigma R \to R \) for some type \( R \), it holds that

\[
f ((\text{liftAlgCont alg}) g) k = \text{Cont} (\lambda q \to f \ \text{alg} \ g ((\lambda m \to \text{runCont m q}) \cdot k))
\]

for any \( g \) and \( k \).

Proof. It is sufficient to show that for any type \( a \) and any \( q :: a \to R \),

\[
\text{runCont} (f ((\text{liftAlgCont alg}) g) k) q = f \ \text{alg} \ g ((\lambda m \to \text{runCont m q}) \cdot k)
\]
This is a consequence of the parametricity of $f$ because $\lambda m \to \text{runCont} m q$ is a $\Sigma$-algebra homomorphism from
\[
\text{liftAlgCont alg} :: \Sigma (\text{Cont}_R a) \to \text{Cont}_R a \\
\text{liftAlgCont alg s} = \text{cont} (\lambda k \to \text{alg} (\text{fmap} (\lambda m \to \text{runCont} m k) s))
\]
to $\text{alg} :: \Sigma R \to R$. □

**Theorem D.2** (Preservation of Equations). Suppose $h_1$ and $h_2$ are modular handlers of signatures $\Sigma_1$ and $\Sigma_2$ respectively. If $h_1$ and $h_2$ are correct open (resp. closed) handlers of $T_1 :: \text{Theory} \Sigma_1$ and $T_2 :: \text{Theory} \Sigma_2$ correspondingly, then $h_2 \circ h_1$ is a correct open (resp. closed) handler of $T_1 + T_2$.

**Proof.** By Definition 2.3, each equation $\text{Eqn}_C \text{lhs rhs}$ of $T_1 + T_2$ is either an equation from $T_1$ or an equation from $T_2$ lifted to signature $\Sigma_1 + \Sigma_2$. If it is from $\text{Eqn}_C \text{lhs' rhs'} :: \text{Equation}_C \Sigma_1 \Gamma V$ from $T_1$, then
\[
\text{lhs, rhs} :: \forall c. ( (\Sigma_1 + \Sigma_2) c \to c ) \to \Gamma \to ( V \to c ) \to c \\
\text{lhs alg} = \text{lhs'} (\text{alg} \cdot \text{Inl}) \\
\text{rhs alg} = \text{rhs'} (\text{alg} \cdot \text{Inl})
\]
Then
\[
\text{lhs alg} ( h_2 \circ h_1 ) = \text{rhs alg} ( h_2 \circ h_1 ) \\
\iff \text{lhs'} ( h_2 \circ h_1 ) \cdot \text{Inl} = \text{rhs'} ( h_2 \circ h_1 ) \cdot \text{Inl} \\
\iff \{ \text{definition of \text{alg} ( h_2 \circ h_1 )} \} \\
\text{lhs'} ( h_2 \circ h_1 ) = \text{lhs'} (\text{alg} h_1)
\]
The last line holds because $h_1$ is a correct handler of $\text{lhs'} = \text{rhs'}$ by assumption.

If $\text{Eqn}_C \text{lhs rhs}$ is from $T_2$, then
\[
\text{lhs, rhs} :: \forall c. ( (\Sigma_1 + \Sigma_2) c \to c ) \to \Gamma \to ( V \to c ) \to c \\
\text{lhs alg} = \text{lhs'} (\text{alg} \cdot \text{Inr}) \\
\text{rhs alg} = \text{rhs'} (\text{alg} \cdot \text{Inr})
\]
By definition,
\[
\text{alg} ( h_2 \circ h_1 ) (\text{Inr op}) = (\text{Fuse} \cdot \text{fwd} \cdot \text{liftAlgCont} (\text{alg} h_2) \cdot \text{fmap} (\text{return} \cdot \text{unFuse})) \cdot \text{op}
\]
By Lemma C.2, to show that $\text{alg} ( h_2 \circ h_1 )$ respects $\text{lhs} = \text{rhs}$, it is sufficient to show that
\[
\text{liftAlgCont} (\text{alg} h_2) :: \text{Monad} m \Rightarrow \Sigma_2 (\text{Cont}_{C_2} m a) \to \text{Cont}_{C_2} m a
\]
respects $\text{lhs'} = \text{rhs'}$ for any $m$ and $a$. Then for any $g$ and $k$,
\[
\text{lhs'} (\text{liftAlgCont} (\text{alg} h_2)) g k \\
= \{ \text{Lemma D.1} \} \\
\text{Cont}_{\lambda q \to \text{lhs'}} (\text{alg} h_2) g ((\lambda m \to \text{runCont} m q) \cdot k) \\
= \{ \text{assumption that \text{alg} h_2 respects \text{lhs'} = \text{rhs'}} \} \\
\text{Cont}_{\lambda q \to \text{rhs'}} (\text{alg} h_2) g ((\lambda m \to \text{runCont} m q) \cdot k) \\
= \text{lhs'} (\text{liftAlgCont} (\text{alg} h_2)) g k \\
= \{ \text{Lemma D.1} \}
\]
□

**E MISCELLANEOUS CALCULATIONS**

This section contains the calculations omitted in the main text. Most of them are straightforward equational proofs.

Eilenberg-Moore Laws for the Fused Modular Carrier

In Theorem 5.2 we define the fused modular carrier to be

```haskell
newtype Fuse c d m = Fuse { unFuse :: c (Cont d m) }
```

with the following `fwd` function:

```haskell
instance (MCARRIER c, MCARRIER d) ⇒ MCARRIER ( Fuse c d ) where
  fwd = Fuse ∙ fwdc ∙ fmap unFuse ∙ reflectEM
  reflectEM :: (MCARRIER d, Monad m) ⇒ m a → Cont d m a
  reflectEM m = Cont (λk → fwd (fmap k m))
```

Here we prove that this `fwd` instance indeed satisfies the Eilenberg-Moore laws (14). For the first equation `fwd ∙ return = id` in (14):

```haskell
fwd (return x)
= (Fuse ∙ fwdc ∙ fmap unFuse) (reflectEM (return x))
= (Fuse ∙ fwdc ∙ fmap unFuse) (Cont (λk → fwdd (fmap k (return x))))
= (Fuse ∙ fwdc ∙ fmap unFuse) (Cont (λk → fwdd (return (k x)))
  ▼ fwdd ∙ return = id
= (Fuse ∙ fwdc ∙ fmap unFuse) (Cont (λk → k x))
= (Fuse ∙ fwdc) (Cont (λk → k (unFuse x)))
= (Fuse ∙ fwdc) (returnCont (unFuse x))
  ▼ fwdc ∙ return = id
= Fuse (unFuse x)
= x
```

For the second equation `fwd ∙ fmap fwd = fwd ∙ join`,

```haskell
fwd ∙ fmap fwd
= Fuse ∙ fwdc ∙ fmap unFuse ∙ reflectEM ∙ fmap (Fuse ∙ fwdc ∙ fmap unFuse ∙ reflectEM)
  ▼ Naturality
= Fuse ∙ fwdc ∙ fmap unFuse ∙ fmap (Fuse ∙ fwdc ∙ fmap unFuse) ∙ reflectEM ∙ fmap reflectEM
  ▼ refl ∙ unFuse ∙ Fuse = id
= Fuse ∙ fwdc ∙ fmap (fwdc ∙ fmap unFuse) ∙ reflectEM ∙ fmap reflectEM
  ▼ refl ∙ fwdc ∙ join = twdc ∙ fmap fwdc
= Fuse ∙ fwdc ∙ join ∙ fmap unFuse ∙ reflectEM ∙ fmap reflectEM
  ▼ Naturality
= Fuse ∙ fwdc ∙ fmap unFuse ∙ join ∙ reflectEM ∙ fmap reflectEM
  ▼ reflectEM is a monad morphism preserving join
= Fuse ∙ fwdc ∙ fmap unFuse ∙ reflectEM ∙ join
= fwd ∙ join
```

Calculations for Clauses of Fused Handler

This subsection provides the detailed calculations for Lemma 5.6 and Lemma 5.7.

Proof of Lemma 5.6. The clause for $O_1$ of $h_2 \circ h_1$ is easy to calculate:

$$\overline{C_I} \ p \ k
= \mathrm{alg} \ (h_2 \circ h_1) \ (\text{Inl} \ (O_1 \ p \ k))$$
Reasoning about Effect Interaction by Fusion

The clause for \( O_2 \) needs some calculation to expand \( \text{liftAlgCont} \):

\[
\bar{c}_2 \ p \ k \\
= \text{alg} \ (h_2 \circ h_1) \ (\text{Inr} \ (O_2 \ p \ k))
\]

\[
= \{ \ \downarrow \ \text{Definition of } h_2 \circ h_1 \ (\text{Theorem 5.3}) \}
\]

\[
\text{liftAlgF} \ (\text{alg} \ h_3) \ (O_2 \ p \ k)
\]

\[
= \{ \ \downarrow \ \text{Definition of } \text{liftAlgF} \ (5.2) \}
\]

\[
(\text{Fuse} \cdot \text{fwd} \cdot \text{liftAlgCont} (\text{alg} \ h_2) \cdot \text{fmap} \ (\text{return} \cdot \text{unFuse})) \ (O_2 \ p \ k)
\]

\[
= \{ \ \downarrow \ \text{Definition of } \text{liftAlgCont} \ (17) \}
\]

\[
\text{Fuse} \ (\text{fwd} \ (\text{Cont} \ (\lambda t \to \text{alg} \ h_2 \ (\text{fmap} \ (\lambda m \to \text{runCont} \ m \ t) \ (O_2 \ p \ (\text{return} \cdot \text{unFuse} \cdot k))))))
\]

\[
= \{ \ \downarrow \ \text{Expanding function composition} \}
\]

\[
\text{Fuse} \ (\text{fwd} \ (\text{Cont} \ (\lambda t \to \text{alg} \ h_2 \ (O_2 \ p \ (\lambda a_2 \to \text{runCont} \ (\text{return} \ (\text{unFuse} \ (k \ a_2))) \ t)))))
\]

\[
= \{ \ \downarrow \ \text{Expanding return and } \text{runCont} \ (16) \}
\]

\[
\text{Fuse} \ (\text{fwd} \ (\text{Cont} \ (\lambda t \to c_2 \ (\lambda a_2 \to t \ (\text{unFuse} \ (k \ a_2))))))
\]

**Proof of Lemma 5.7.** When the modular carrier \( c \) of the first handler is \( \text{FreeEM} \ W \) for some type \( W \), we can simplify \( \bar{c}_2 \):

\[
\bar{c}_2 \ p \ k
\]

\[
= \text{Fuse} \ (\text{fwd} \ (\text{Cont} \ (\lambda t \to c_2 \ p \ (\lambda a_2 \to t \ (\text{unFuse} \ (k \ a_2))))))
\]

\[
= \{ \ \downarrow \ \text{Definition of } \text{fwd} \text{ for } \text{FreeEM} \ (\text{Example 3.5}) \}
\]

\[
\text{Fuse} \ (\text{FreeEM} \cdot \text{join} \cdot \text{fmap} \ \text{unFreeEM} \ (\text{Cont} \ (\lambda t \to c_2 \ p \ (\lambda a_2 \to t \ (\text{unFuse} \ (k \ a_2))))))
\]

\[
= \{ \ \downarrow \ \text{fmap of } \text{Cont} \}
\]

\[
\text{Fuse} \ (\text{FreeEM} \ (\text{join} \ (\text{Cont} \ (\lambda t \to c_2 \ p \ (\lambda a_2 \to t \ (\text{unFreeEM} \ (\text{unFuse} \ (k \ a_2)))))\ (\lambda x \to \text{runCont} \ x \ q)))
\]

\[
= \{ \ \downarrow \ \text{Eliminating } \text{runCont} \}
\]

\[
\text{Fuse} \ (\text{FreeEM} \ (\text{Cont} \ (\lambda q \to \text{runCont} \ (\text{Cont} \ (\lambda t \to c_2 \ p \ (\lambda a_2 \to t \ (\text{unFreeEM} \ (\text{unFuse} \ (k \ a_2)))))\ (\lambda x \to \text{runCont} \ x \ q)))
\]

\[
= \{ \ \downarrow \ \text{Letting } k' = \text{runCont} \cdot \text{unFreeEM} \cdot \text{unFuse} \cdot k\}
\]

\[
\text{Fuse} \ (\text{FreeEM} \ (\text{Cont} \ (\lambda q \to c_2 \ p \ (\lambda a_2 \to k' \ a_2 \ q)))
\]

Similarly, when the modular carrier is \( \text{StateC} \ S \ W \) for some \( S \) and \( W \), we can simplify \( \bar{c}_2 \) by

\[
\bar{c}_2 \ p \ k
\]

\[
= \text{Fuse} \ (\text{fwd} \ (\text{Cont} \ (\lambda t \to c_2 \ p \ (\lambda a_2 \to t \ (\text{unFuse} \ (k \ a_2))))))
\]
= \{ \downarrow \text{Definition of fwd for StateC (Example 3.6)} \}
\text{let } mc = \text{Cont (}\lambda t \rightarrow c_2 \ p (\lambda a_2 \rightarrow t (\text{unFuse (}\ k \ a_2))))\text{ in Fuse (}\text{StateC (}\lambda s \rightarrow (\text{do } \{ f \leftarrow mc; \text{unStateC f s}\})})\}
= \{ \downarrow \text{Expanding } \Rightarrow \text{ for Cont } \}
\text{Fuse (}\text{StateC (}\lambda s \rightarrow \text{Cont (}\lambda q \rightarrow \text{runCont (}\text{Cont (}\lambda t \rightarrow c_2 \ p (\lambda a_2 \rightarrow t (\text{unFuse (}\ k \ a_2)))))(\lambda f \rightarrow \text{runCont (}\text{unStateC f s q})))\}
= \{ \downarrow \text{Applying functions} \}
\text{Fuse (}\text{StateC (}\lambda s \rightarrow \text{Cont (}\lambda q \rightarrow c_2 \ p (\lambda a_2 \rightarrow \text{runCont (}\text{unStateC (}\text{unFuse (}\ k \ a_2)) \ s q)\}))\}
= \{ \downarrow \text{Letting } k' \ a_2 \ s = \text{runCont (}\text{unStateC (}\text{unFuse (}\ k \ a_2)) \ s)\}\}
\text{Fuse (}\text{StateC (}\lambda s \rightarrow \text{Cont (}\lambda q \rightarrow c_2 \ p (\lambda a_2 \rightarrow k' \ a_2 \ s q))}}\}

E.3 Local State Semantics from the Tensor
The following is the proof for our claim in Remark 6.1 that the laws of the local state semantics from [Pauwels et al. 2019] can be derived from the laws of the tensor of mutable state and nondeterminism. The laws in [Pauwels et al. 2019] are

\begin{align*}
m \Rightarrow (\_ \rightarrow \text{fail}) &= \text{fail} \
m \Rightarrow (\lambda x \rightarrow f_1 \ x \sqcap f_2 \ x) &= (m \Rightarrow f_1) \cap (m \Rightarrow f_2)
\end{align*}

where \(m\) ranges over computations in the combined theory. The first equation includes a nullary operation \(\text{fail}\) that fails a branch of nondeterminism subject to the equations

\begin{align*}
\text{fail} \sqcap m &= \text{fail} \\
m \sqcap \text{fail} &= \text{fail}
\end{align*}

(44)

which we did not include in the theory of nondeterminism in this paper. But this is easily fixable: \(\text{ndetH}\) can be extended to handle \(\text{fail}\) by returning an empty set, and it can be verified to respect the laws of \(\text{fail}\). In the following, we show that for any \(m :: \text{Free (}\text{State}_s + \text{NDet}) \ a\), (42) and (43) hold when applying \(\text{handle h}\) to both sides of the equations, for any handler \(h\) that is correct for the tensor \(\text{State}_s \otimes \text{NDet}\) and any \(m :: \text{Free (}\text{State}_s + \text{NDet}) \ a\).

For (42), we prove by induction on \(m\): if \(m\) is \(\text{Var} x\) for some \(x\), \(\text{Var} x \Rightarrow \_ \rightarrow \text{fail} = \text{fail}\) holds directly. If \(m\) is \(O p k\) for some \(O, p\) and \(k\), and if \(O\) is an operation from \(\text{State}_s\),

\[\text{handle h (} O p k \Rightarrow \_ \rightarrow \text{fail}) = \text{handle h (}\text{do } \{ O p k; \text{fail}\})\]
\[= \{ \downarrow \text{Handler h respects the tensor of NDet and State}_s \}
\text{handle h (}\text{do } \{ x \leftarrow \text{fail}; O p k; \text{return} x\})\]
\[= \{ \downarrow \text{fail is a nullary operation} \}
\text{handle h fail}\]

If \(O\) is an operation from \(\text{NDet}\), the calculation above still holds because \(\text{fail}\) is commutative with any operations of \(\text{NDet}\) following the laws (44).

For (43), we also prove by induction on \(m\): if \(m\) is \(\text{Var} x\) for some \(x\),

\[m \Rightarrow (\lambda x \rightarrow f_1 \ x \sqcap f_2 \ x) = \text{Var} x \Rightarrow (\lambda x \rightarrow f_1 \ x \sqcap f_2 \ x)\]
\[= f_1 \ x \sqcap f_2 \ x\]
\[= (m \Rightarrow f_1) \cap (m \Rightarrow f_2)\]
if \( m \) is some \( O p k \) and if \( O \) is from \( \text{State}_s \),
\[
\text{handle } h \ (m \Rightarrow (\lambda x \rightarrow f_1 \ x \cap f_2 \ x)) \\
= \text{handle } h \ (O p k \Rightarrow (\lambda x \rightarrow f_1 \ x \cap f_2 \ x)) \\
= \text{handle } h \ (O p (\lambda a \rightarrow f_1 \ (k \ a) \cap f_2 \ (k \ a))) \\
= \{ \text{The commutativity of state operation } O \text{ and } \cap \} \\
\text{handle } h \ (O p (f_1 : k) \cap O p (f_2 : k)) \\
= \text{handle } h \ ((m \Rightarrow f_1) \cap (m \Rightarrow f_2))
\]
Additionally, the calculation above still holds when \( O \) is some operation from \( \text{NDet} \) because \( \cap \) is commutative with any operation of \( \text{NDet} \) following the laws of \( \text{NDet} \).

## E.4 Correctness for the Global State Semantics

The following is a proof for the claim in Remark 6.2 that the composite handler \( st \ s \odot \text{ndetH} \) is a correct closed handler of the global state semantics from [Pauwels et al. 2019]. In the \textit{put-or} law,
\[
(Put \ s \ (\lambda l : m) \cap n) = Put \ s \ (\lambda l : m \cap n)
\]
(45)
Operation \( \text{Put} \) is from the second handler \( st \ s \), and the modular carrier of first handler \( \text{ndetH} \) is \( \text{FreeEM} \). Thus by Lemma 5.7, the clause for \( \text{Put} \) of \( st \ s \odot \text{ndetH} \) is
\[
\overline{c_{\text{Put}}} \ p_2 \ k \\
= \text{Fuse} \ (\text{FreeEM} \ (\text{Cont} \ (\lambda q \rightarrow c_{\text{Put}} \ p_2 \ (\lambda a_2 \rightarrow k' \ a_2 \ q)))) \\
| \ \{} \text{the clause is the case for } \text{Put} \text{ of } stH \} \\
= \text{Fuse} \ (\text{FreeEM} \ (\text{Cont} \ (\lambda q \rightarrow \text{StateC} \ (\lambda s \rightarrow \text{unStateC} \ (k' \ q) \ p_2)) \\
\text{where } k' = \text{runCont} \cdot \text{unFreeEM} \cdot \text{unFuse} \cdot \ k. \text{ And the clause for } (\cap), \text{ i.e. } \text{Coin} \text{ is }
\overline{c_{\text{Coin}}} \ () \ k = \text{Fuse} \ (\text{FreeEM} \ (\text{do} \ l_1 \leftarrow \text{unFreeEM} \ (\text{unFuse} \ (k \ True)) \ l_2 \leftarrow \text{unFreeEM} \ (\text{unFuse} \ (k \ False)) \ return \ (l_1 \cup l_2)))
\]
For any \( m, n \), plugging in \( \overline{c_{\text{Put}}} \) and \( \overline{c_{\text{Coin}}} \) in (45) gives
\[
(Put \ s \ (\lambda l : m) \cap n) = \overline{c_{\text{Coin}}} \ () \ b \rightarrow \text{if } b \text{ then } \overline{c_{\text{Put}}} \ s \ (\lambda l : m) \text{ else } n) \\
= \text{Fuse} \ (\text{FreeEM} \ (\text{do} \ l_1 \leftarrow \text{unFusedEM} \ (\text{unFuse} \ \overline{c_{\text{Put}}} \ s \ (\lambda l : m))) \\
| \ l_2 \leftarrow \text{unFreeEM} \ (\text{unFuse} \ n) \\
| \ return \ (l_1 \cup l_2))) \\
| \ \{} \text{Letting } m' = \text{unFreeEM} \ (\text{unFuse} \ m) \text{ and } n' = \text{unFreeEM} \ (\text{unFuse} \ n) \} \\
= \text{Fuse} \ (\text{FreeEM} \ (\text{do} \ l_1 \leftarrow \text{Cont} \ (\lambda q \rightarrow \text{StateC} \ (\_ \rightarrow \text{unStateC} \ (\_ \rightarrow \text{unStateC} \ (\text{runCont} \ m' \ q) \ s)) \\
| \ l_2 \leftarrow n' \\
| \ return \ (l_1 \cup l_2))) \\
| \ \{} \text{Expanding } \text{do-notation for } \text{Cont} \} \\
= \text{Fuse} \ (\text{FreeEM} \ (\text{Cont} \ (\lambda t \rightarrow \text{StateC} \ (\_ \rightarrow \text{unStateC} \ (m' \ (\lambda l_1 \rightarrow n' \ (\lambda l_2 \rightarrow t \ (l_1 \cup l_2)))) \ s))) \\
| \ \{} \text{Expanding } \text{do-notation for } \text{Cont} \} \\
= \text{Fuse} \ (\text{FreeEM} \ (\text{Cont} \ (\lambda t \rightarrow \text{StateC} \ (\_ \rightarrow \text{unStateC} \ ( \text{runCont} \ (\text{unFreeEM} \ (\text{unFuse} \ (\text{do} \ l_1 \leftarrow m'; l_2 \leftarrow n'; \text{return} \ (l_1 \cup l_2)))) \ t) \ s)))) \\
| \ \{} \text{Expanding } \overline{c_{\text{Coin}}} \} \\
= \text{Fuse} \ (\text{FreeEM} \ (\text{Cont} \ (\lambda t \rightarrow \text{StateC} \ (\_ \rightarrow \text{unStateC} \ (} \)
runCont \( (\text{unFreeEM} \ (\text{unFuse} \ (c_{\text{coin}} \ (\lambda b \rightarrow \text{if } b \text{ then } m \text{ else } n)))) \)  
\( t \)  
\)  
\( s \)  
\( \lambda (\rightarrow c_{\text{coin}} \ (\lambda b \rightarrow \text{if } b \text{ then } m \text{ else } n)) \)  
\( s \)  
\( \lambda (\rightarrow m \cap n) \)  
This establishes (45).  

### E.5 Correctness of the Writer Handler  

**Lemma E.1.** Handler \( \text{wtH} \) in Section 6.2 is a correct open handler of the theory of writer effect with equation \( \text{wtAdd} \).

**Proof.** The accumulation law (see Section 6.2) can be formalised by

\[
\text{wtAdd} :: \text{Monoid } w \Rightarrow \text{Equation}_C (\text{Writer } w) (w, w) ()
\]

\[
\text{wtAdd} = \text{Eqn}_C \text{ lhs rhs where}
\]

\[
\text{lhs alg } (w_1, w_2) k = \text{alg } (\text{Tell } w_1 (\lambda (\rightarrow \text{alg } (\text{Tell } w_2 k)))
\]

\[
\text{rhs alg } (w_1, w_2) k = \text{alg } (\text{Tell } (w_1 \odot w_2) k)
\]

Let \( \text{lhs} \) and \( \text{rhs} \) be the two sides of the equation, \( w_1, w_2 :: w \) and \( k :: () \rightarrow \text{FreeEM } (a, w) \) \( m \), then

\[
\text{lhs alg wtH } (w_1, w_2) k
\]

\[
= \{ \downarrow \text{ definition of lhs } \}
\]

\[
\text{alg wtH } (\text{Tell } w_1 (\text{alg wtH } (\text{Tell } w_2 (k ())))))
\]

\[
= \{ \downarrow \text{ definition of alg wtH on Tell } \}
\]

\[
\text{alg wtH } (\text{Tell } w_1 \ (\text{FreeEM } (\text{do } \{(a, w) \leftarrow \text{unFreeEM } (k ()) \}
\]

\[
\text{return } (a, w_2 \odot w))}))
\]

\[
= \{ \downarrow \text{ definition of alg wtH on Tell } \}
\]

\[
\text{FreeEM } \ (\text{do } \{(b, u) \leftarrow \text{unFreeEM } (k ()) \}
\]

\[
\text{return } (a, w_2 \odot w))
\]

\[
= \{ \downarrow \text{ monadic properties } \}
\]

\[
\text{FreeEM } \ (\text{do } \{(a, w) \leftarrow \text{unFreeEM } (k ()) \}
\]

\[
\text{return } (a, w_1 \odot (w_2 \odot w)))))
\]

\[
= \{ \downarrow \text{ monoid law: } w_1 \odot (w_2 \odot w) = (w_1 \odot w_2) \odot w \}
\]

\[
\text{alg wtH } (\text{Tell } (w_1 \odot w_2) (k ()))
\]

\[
= \{ \uparrow \text{ definition of rhs } \}
\]

\[
\text{rhs alg wtH } (w_1, w_2) k
\]

\( \square \)

**Theorem E.2 (Theorem 6.6).** Both \( \text{stH} \odot \text{wtH} \) and \( \text{wtH} \odot \text{stH} \) are correct open handlers of the tensor of mutable state and writer.

**Proof.** Following Theorem 6.5, \( \text{wtH} \odot \text{stH} \) \( s \) is a correct open handler of the tensor. To show that \( \text{stH} \odot \text{wtH} \) is correct, we apply Corollary 6.2. For \( \text{op}_1 = \text{Tell} \) and \( \text{op}_2 = \text{Put} \), we have

\[
c_1' \ p \ k = \text{runCont } (\text{unFreeEM } (c_1 \ p \ (\text{FreeEM} \cdot \text{Cont} \cdot k)))
\]

\[
= \text{runCont } (\text{do } \{(a, u) \leftarrow \text{Cont } (k ()); \text{return } (a, p \odot u)})
\]

\[
= \lambda q \rightarrow k (\lambda (a, u) \rightarrow q (a, p \odot u))
\]

\[ c_2 \cdot p \cdot k = \text{StateC} (\lambda s \rightarrow \text{unStateC} (k (\, ) \, p) \]

and we establish (21) by the following calculation:

\[
\begin{align*}
& c'_1 \cdot p_1 \cdot (\lambda a_1 \rightarrow (\lambda q \rightarrow c_2 \cdot p_2 \cdot (\lambda a_2 \rightarrow k' \cdot a_1 \cdot a_2 \cdot q))))) & \{ \downarrow \text{ expanding } c_2 \} \\
& = c'_1 \cdot p_1 \cdot (\lambda a_1 \rightarrow (\lambda q \rightarrow \text{StateC} (\lambda s \rightarrow \text{unStateC} (k' \cdot a_1 \cdot (\, ) \cdot q) \cdot p_2))) & \{ \downarrow \text{ expanding } c_1 \} \\
& = \lambda q \rightarrow \text{StateC} (\lambda s \rightarrow \text{unStateC} (k' \cdot (\, ) \cdot (\lambda (a, u) \rightarrow q \cdot (a, p_1 \circ u)) \cdot p_2)) & \{ \uparrow \text{ expanding } c_1 \} \\
& = \lambda q \rightarrow \text{StateC} (\lambda s \rightarrow \text{unStateC} (c'_1 \cdot p_1 \cdot (\lambda a_1 \rightarrow k' \cdot a_1 \cdot (\, ) \cdot q) \cdot p_2) & \{ \uparrow \text{ expanding } c_2 \} \\
& = \lambda q \rightarrow c_2 \cdot p_2 \cdot (\lambda a_2 \rightarrow c'_1 \cdot p_1 \cdot (\lambda a_1 \rightarrow k' \cdot a_1 \cdot a_2 \cdot q)
\end{align*}
\]

For \( op_1 = \text{Tell} \) and \( op_2 = \text{Get}, \) we can similarly show that both sides of Equation 21 are equal to

\[
\lambda q \rightarrow \text{StateC} (\lambda s \rightarrow k' \cdot (\, ) \cdot s \cdot (\lambda (a, u) \rightarrow q \cdot (a, p_1 \circ u)) \cdot s)
\]

By Corollary 6.2 we conclude that \( stH \cdot s \circ wtH \) correctly handles the tensor. \( \square \)

## F A SIMPLE LANGUAGE FOR MODULAR HANDLERS

This section shows a fine-grained call-by-value [Levy 2003] language \( \lambda_M \) with effect handlers, its type system, and a denotational semantics based on the constructions discussed in this paper. The language is similar to the language core \( \text{Eff} \) in [Bauer and Pretnar 2015] except that the type system of \( \lambda_M \) requires handlers to work polymorphically in unhandled operations, so handlers in \( \lambda_M \) are always modular handlers.

### F.1 Abstract Syntax

Let \( m, n, p, k, x, \) and \( y \) range over a set of variables, and \( op \) range over a set of operation symbols. The types of \( \lambda_M \) are split into computation types and value types, and a subset of value types are ground types, which does not contain functions and handlers.

- **Ground types**
  
  \[ G, P ::= \Pi_{i \in I} G_i \mid \Pi_{i \in I} G_i \]

- **Value types**
  
  \[ A, B ::= G \mid A \rightarrow C \mid A \Rightarrow \Sigma B \mid \Pi_{i \in I} A_i \mid \Pi_{i \in I} A_i \]

- **Computation types**
  
  \[ C, D ::= M A \]

- **Effects**
  
  \[ M ::= F_{\Sigma} \mid m \]

- **Signatures**
  
  \[ \Sigma ::= \{ op_i : P \rightarrow G \}_{i \in I} \]

where the index set \( I \) is always finite. Note that when \( I \) is the empty set, the product type \( \Pi\{\} \) can be used as the unit type and the coproduct type \( \Pi\{\} \) can be used as the empty type. Therefore we do not need these base types in the language.

The terms of \( \lambda_M \) are split into two syntactic categories: pure values and potentially effectful computations:

- **Values**
  
  \[ \upsilon ::= x \mid \text{inj}_{i \in I} \upsilon \mid \langle \upsilon_i \rangle_{i \in I} \mid \lambda x : A. c \mid \text{Hdl}_{\Sigma}\{ \text{val} \ x \mapsto e \mid (\text{op} \ p \ k \mapsto c)_{op \in \Sigma} \} \]

- **Computations**
  
  \[ c ::= \text{val} \ \upsilon \mid \text{op} \ \upsilon \ (y, c) \mid \text{with} \ \upsilon \ \text{handle} \ c \mid \upsilon \ \upsilon \\
  \mid \text{let} \ x = c \ \text{in} \ c \mid \text{match} \ e \ \text{as} \ \{ \langle x_i \rangle_{i \in I} \mapsto c \} \]

### F.2 Type System

Let \( \Gamma \) range over finite maps from variables to value types and \( \Delta \) be finite set of variables. We say a type is well-formed under \( \Delta \) if all effect variables \( m \) in the type are contained in \( \Delta, \) and
well-formedness is signified by judgements
\[ \Delta \vdash A \quad \text{and} \quad \Delta \vdash C \]
for both value types and computation types. We also have two typing judgements:
\[ \Delta \vdash v : A \quad \Delta \vdash c : C \]
where \( A, C \) and \( \Gamma(\Delta) \) for each \( x \in \text{dom}(\Gamma) \) are well-formed under \( \Delta \). The typing rules for values types are the following:
\[ (x : A) \in \Gamma \quad \Delta \vdash x : A_j \quad \Delta \vdash \text{inj}_j : \Pi_{i \in I} A_i \quad \Delta \vdash \text{x}_I : A_i \text{ for each } i \in I \]
\[ \Delta \vdash \lambda x : A. c : A \rightarrow C \]
\[ m \notin \Delta \quad x \notin \text{dom}(\Gamma) \quad \{p_i, k_i\}_{op_i \in \Sigma} \cap \text{dom}(\Gamma) = \emptyset \]
\[ \Delta, m \vdash \Gamma, x : A \vdash c_0 : m B \]
\[ \Delta \vdash \text{Hdl}_\Sigma \{\text{val } x \mapsto c_0 \mid (\text{op}_i p_i k_i \mapsto c_i)_{op_i \in \Sigma} \} : A \rightarrow_{\Sigma} B \]

and the typing rules for computations are
\[ \Delta \vdash v : A \Rightarrow B \quad \Delta \vdash c : F_{\Sigma} A \quad \Delta \vdash v_1 : A \rightarrow C \quad \Delta \vdash v_2 : A \]
\[ \Delta \vdash \text{let } x = c_1 \text{ in } c_2 : M B \]

F.3 Denotational Semantics

In the following we show a denotational semantics of \( \lambda_M \) by translating typing derivations to Haskell functions. As we mentioned in Section 2, we meant to use Haskell as a total language denoting constructions around the category of sets. Thus the translation can be understood as a set-theoretic semantics of \( \lambda_M \).

**Denotation of Types.** Assuming there is an injective map \( \rho \) from variables in \( \lambda_M \) to Haskell type variables of kind \( * \rightarrow * \). For any well-formed type \( A \) or \( C \) under \( \Delta \), its semantics is a Haskell type \( [A]_\rho \) or \( [C]_\rho \), in which variables in \( \{\rho(m) \mid m \in \Delta\} \) may occur freely. (Categorically, the meaning of a type is a profunctor \((\text{Mnd}^\Delta)^{op} \times \text{Mnd}^\Delta \rightarrow \text{Set}\) where \(\text{Mnd}^\Delta\) is the \(|\Delta|\)-fold product category of the category of set monads).
Unsurprisingly, the product type Π denotes tuples in Haskell: \( [\Pi_{i \in I} A_i]_\rho = ([A_i]_\rho)_{i \in I} \). Coproduct types Π denote finite coproducts of Haskell types too, but Haskell does not have a syntax for nameless finite coproducts, so we translate \( [\Pi_{i \in I} A_i]_\rho \) into a datatype declaration:

\[
data T = (\text{In}_{i} [A_i]_\rho)_{i \in I}
\]

where \( T \) is a fresh name in the translation. Function types \( A \rightarrow C \) denote functions \([A]_\rho \rightarrow [C]_\rho\). Signatures \( \Sigma \) denote signature functors as in Section 2.1:

\[
data S x = \left( Op_i [P_i]_\rho \ (A_i \rightarrow x) \right)_{(\text{op}_i, P_i \rightarrow A_i) \in \Sigma}
\]

where \( S \) and \( Op_i \) are fresh names for the translation. Handler types \( A \Rightarrow \_ \) denote signature functors as in Section 3.3. For computations, \([F \Sigma \ A]_\rho \) is precisely \([Free \Sigma \ [A]_\rho]_\rho\), and \([m \ A]_\rho \) is \( \rho(m) [A]_\rho\).

**Denotation of Terms.** Given a context \( \Gamma \) mapping to well-formed types under \( \Delta \), its meaning \([\Gamma]_\rho \) is the product type of the meaning of the types that \( \Gamma \) mapped to. Then the meaning of a typing derivation \( \Delta \mid \Gamma \vdash v : A \) or \( \Delta \mid \Gamma \vdash c : C \) is some Haskell function of type

\[
\forall (\rho(m))_{m \in \Delta}. \ (\text{Monad } \rho(m))_{m \in \Delta} \Rightarrow [\Gamma]_\rho \rightarrow [A]_\rho
\]

or

\[
\forall (\rho(m))_{m \in \Delta}. \ (\text{Monad } \rho(m))_{m \in \Delta} \Rightarrow [\Gamma]_\rho \rightarrow [C]_\rho
\]

For most cases in the type system, their meanings are standard (see for example [Levy 2003] and [Bauer and Pretnar 2015]), thus we only describe the non-standard cases here:

- For rule T-HdI, the meaning of a handler value \( \text{Hd1}_\Sigma \{ \text{val} \ x \mapsto c_0 | (\text{op}_i \ p_i \ k_i \mapsto c_i)_{\text{op}_i, \Sigma} \} \rho \) is a function \( f \) of type

\[
\forall (\rho(m))_{m \in \Delta}. \ (\text{Monad } \rho(m))_{m \in \Delta} \Rightarrow [\Gamma]_\rho \rightarrow (\text{MHandler} \ [\Sigma]_\rho \ (\text{FreeEM} \ [B]_\rho)) \ [A]_\rho \ [B]_\rho
\]

defined by

\[
f \ g = \text{MHandler} \ \{ \text{gen} = (\lambda a \rightarrow [c_0]_\rho \ (g, a)) \ 
, \text{alg} = (\lambda x \rightarrow \text{case } x \ \text{of} \ \{(\text{op}_i \ p \ k) \rightarrow [c_i]_\rho \ (g, p, k) \ 
\cdots \}) \ 
, \text{run} = \text{unFusedEM} \}
\]

- For rule T-RET, \([M \ A]_\rho\) is either \([Free \ [\Sigma]_\rho \ [A]_\rho]_\rho\) or \(\rho(m) [A]_\rho\), and \(\rho(m)\) is given a monad constraint when defining the meaning of \(\text{val} \ v\). Thus we can interpret \(\text{val} \ v\) by the return of \([M]_\rho\):

\[
[\text{val} \ v]_\rho \ g = \text{return} \ ([v]_\rho \ g)
\]

- For rule T-BIND, it is interpreted by \(\Rightarrow\) of \([M]_\rho\):

\[
[\text{let } x = c_1 \ \text{in } c_2]_\rho \ g = ([c_1]_\rho \ g) \Rightarrow (\text{curry} \ ([c_2]_\rho \ g))
\]

- For rule T-OP, it is interpreted by the \text{Op} constructor of the free monad \text{Free}:

\[
[\text{op } v \ (y, c)]_\rho \ g = \text{Op} \ ([v]_\rho \ g) \ (\lambda y \rightarrow [c]_\rho \ (g, y))
\]

- For rule T-WITH, it is interpreted by the \text{handle} function in Section 3:

\[
[\text{with } v \ \text{handle } c]_\rho \ g = \text{handle} \ ([v]_\rho \ g) \ ([c]_\rho \ g)
\]
